Mr. R. WATSON JONES (Liverpool) said that during childhood and adolescence the shoulder was seldom injured. For the purpose of this discussion he had investigated every case of shoulder injury treated in his fracture clinic at Liverpool Royal Infirmary during five years—over 700 cases; he would speak mainly, however, of the 571 cases of dislocation of the upper end of the humerus. Of the 216 shoulder dislocations, only 6 were under 20 years of age. Radiograms clearly differentiated two types of isolated fracture of the great tuberosity. One was a result of direct contusion of the bone; the fragment split off from the end was frequently comminuted and never widely displaced. In the other type the displaced fragment was small, involving only the part of the tuberosity into which the supraspinatus tendon was inserted. It represented the first stage of avulsion of that tendon. If the fragment was not displaced, the functional result was excellent. But if the supraspinatus was completely torn away, the resulting disability might be serious. Dislocations of the shoulder-joint and dislocations with fracture of the great tuberosity should be grouped together, as they were clinically similar. A very different injury was dislocation of the shoulder with fracture of the neck of the humerus. Early forced passive movement was just as disastrous in shoulder dislocations as it was in elbow dislocations. Myositis ossificans was often seen in badly treated dislocations of the shoulder. When the great tuberosity had been torn off, the fragment of bone was usually large; it was found to have been completely reduced when the dislocation was reduced. Avulsion of the supraspinatus was of great importance and it could not be diagnosed until after mobilisation was begun. It was then found that active abduction was recovering more slowly than passive abduction; if the deltoid was seen to be contracting normally the diagnosis was then clear. It was essential to support the arm in a frame with 90° of abduction until active movement was restored. Dislocations and fracture-dislocations of the shoulder were often complicated by nerve lesions; in this series 1 in 7. They were usually traction injuries. An analysis showed that the circumflex nerve was most commonly involved, next in frequency the posterior cord of the plexus and the musculo-spiral. Usually the lesion was a

physiological block, not a complete nerve severance; it was not surprising that nearly every such case recovered after expectant treatment.

It had been customary, said Mr. Watson Jones, to divide fractures of the neck of the humerus into fractures of the anatomical neck and fractures of the surgical neck, but this he regarded as of no value. One natural group was that of fractures produced by a direct blow on the point of the shoulder—i.e., a crack fracture of the neck of the humerus, as a rule, subperiosteal and without displacement, and usually associated with a comminuted fracture of the tuberosity. Treatment and prognosis here were the same as in fractures of the great tuberosity without displacement. Another group was the adduction fracture, the arm being carried inwards. In the elderly patient the adduction fracture should be left impacted, active movement being begun at once; in younger patients the fracture should be manipulated and treated in an abduction frame. A third group was the abduction fracture, with inward angulation, the great tuberosity as a rule being fractured and pinched off. In some cases the tuberosity might not be completely detached, the head being rotated far out. In such a case, after reduction of the fracture, the surgeon might be forced to immobilise the limb in the abducted externally rotated position. If that was done, traction was essential in order to prevent the shaft from sliding back again under the head. Turning to fracture-dislocation, the impacted type could not possibly, he said, be reduced by manipulation. If it was to be reduced at all it must be operated upon, the head disimpacted from the shaft, and the tuberosity replaced. After the Nicola operation, if the proximal fragment bearing the articular cartilage was completely deprived of blood-supply, aseptic necrosis might cause arthritis and ankylosis of the joint. In the unimpacted fracture-dislocation it was well to attempt manipulative reduction. In a dock labourer, aged 42, this treatment had restored him to his heavy work with normal range of movement in all directions. Where aseptic necrosis had caused degenerative arthritis without ankylosis it was advisable to perform arthrodesis. In a doctor, after freshening of the surfaces, he drove a bone-graft through the head of the bone into the glenoid, and the patient still remained an expert boxer. In conclusion, Mr. Watson Jones said that the neck of the humerus was a common site for secondary neoplasms, and pathological fractures were sometimes mistaken for simple ones.

DISCUSSION

Mr. C. H. FRANKAU did not agree with Mr. Perkins that fractures of the neck of the humerus with displacement required operation. His practice had been to keep such cases immobilised for six days, simply bandaging the arms to the sides, and afterwards starting active movements and gentle massage.

Mr. H. A. T. FAIRBANK was glad that both openers had emphasised the drawbacks of abducting most of these fractures. He had often seen cases in which abduction had worsened the condition of the fracture. His own practice was to abduct the arm a little by a pad in the axilla. He had been impressed by the fact that displacement of the great tuberosity was unimportant.

Mr. A. S. BLUNDELL BANKART said that for many years he had been treating fractures of the neck of the humerus in old people by immediate active movements; this had given practically complete mobility of the joint.

Mr. N. L. CAPENER said that sometimes fracture of the greater tuberosity led to supraspinatus strain; this muscle was apt to contract, and, lying so deeply as it did, the effect was difficult to counteract. The result was some limitation of horizontal flexion, with inability to get the arm across the shoulder. The patient should be required to practise touching the opposite shoulder.

Mr. ALAN TODD said the abduction treatment was useful in some cases. The cardinal principle to apply to most fractures in the region of the shoulder was to place the greater fragment which was controllable in line with the lesser fragment which was uncontrollable. If to abduct the greater fragment would cause obvious mal-alignment, then abduction was out of place.

REPLY

Mr. WATSON JONES thought it was possible to be too enthusiastic in mobilisation of shoulder fractures on the first day. Where there was displacement mobilisation should wait for two or three weeks. Torn tissues which were moved too much would repair with a greater amount of scar tissue. Mobilisation of fingers, wrist, and elbow should start at once. The stiffest shoulder was found in the patient with stiff fingers.

Mr. PERKINS remarked that movement should be begun as soon as possible. In fractures around the shoulder-joint it was better to forget the bone and treat the injury as if it was a bruise.

SECTION OF THERAPEUTICS AND PHARMACOLOGY

At a meeting of this section held on March 10th, with Dr. DOROTHY HARE, the president, in the chair, a discussion on the

Treatment of Addison's Disease with Salt

was opened by Dr. GEORGE GRAHAM. In outlining the development of this treatment, he said that Loeb in 1932 had made a complete analysis of the base and acid radicles of the blood in Addison's disease, and shown that there was an escape of sodium, and with it of chlorine, from the blood when the adrenals were removed. Since that time Addison's disease had been treated with salt. It was as if there were a leak through which sodium escaped from the body. It could be controlled by giving cortical extract or by adding more sodium to the reservoir. Patients immediately showed improvement when salt was given to them, and sometimes they could give up their extract altogether or reduce the dose. Dr. Graham then described five cases treated at St. Bartholomew's Hospital in the last two years. One had died in a few days without investigation. Two others had gone out of hospital much improved after salt treatment and had then died within a few days of contracting a febrile illness. It was important to keep in touch with these patients and to make those in charge of them realise that when they contracted feverish illnesses their dose of salt or cortex must be increased, just as the diabetic needed special care in such circumstances. One patient, a man of 34, had had typical Addison's disease with much pigmentation, a blood pressure of 80/50, and a blood sodium of just under 300 mg. per 100 c.c.m., and had been vomiting excessively, very weak, and quite unable to sit up. After a single dose of salt he had felt very much better and had sat up and read the paper.

Dr. S. LEVY SIMPSON pointed out that the high cost, the weak concentration, and the necessity for injections constituted serious disadvantages to cortical treatment. Salt treatment was based on sound experimental and biochemical work and had been received with enthusiasm. Experience had, however, revealed its limitations. He described six cases of Addison's disease which illustrated the value and limitations of salt therapy, and drew the following conclusions: (1) salt by mouth might be of real value in the acute, subacute, and chronic phases of Addison's disease; (2) salt might be of no apparent value or the benefit might be so slight as not to be appreciated by the patient; (3) the emetic action of the chloride might prevent the oral administration, but sometimes salts of sodium other than the chloride might be satisfactorily substituted to overcome this difficulty; (4) 10 g. of salt daily was as much as most patients could possibly take, but sometimes 20 g. or more were necessary; (5) cortical extract in adequate dosage by itself or in addition to salt therapy gave a much better clinical response than salt alone; (6) when the dose of cortical extract was adequate the addition of salt was of no benefit—this was in keeping with work on adrenalectomised animals; when, however, the dose of cortical extract was inadequate, the addition of salt might help appreciably; (7) when patients had gone into a crisis in spite of having large doses of salt, the administration of cortical extract had produced recovery; (8) it was possible to get signs and symptoms of adrenal insufficiency although the serum level of sodium, chloride, and potassium appeared to be within normal limits. These conclusions were in keeping with experimental evidence. The cortical hormone was now known to regulate the balance of sodium chloride and other minerals. Cortical extract aided the sodium leakage by repairing and stopping the leak, but administration of salt was nothing but a frantic effort to keep pace with the abnormal loss. The control of leakage by cortical extract could only be a question of dosage, but the large doses necessary for more severe cases rendered the use of extract difficult and sometimes impracticable. No one could be satisfied with the concentration of the extract at present available, but with the crystallisation of the essential element there would, Dr. Simpson believed, be no other treatment for Addison's disease.

Dr. E. N. ALLOTT described eight cases which he had seen from the beginning of their treatment. Some cases had normal blood-urea readings; a normal blood-urea was not incompatible with Addison's disease. He submitted charts showing the effect of treatment on the urea, the potassium, the sodium, and the chlorine in the blood. One patient who was having a huge dose of cortical extract, up to 60 c.c.m. a day, had shown a reduction of the blood potassium only when salt was added to the cortical treatment. His sodium and chlorine figures had never reached normal. During a crisis there was a fall in the sodium and chloride and a marked rise in the potassium. Curiously, the urea had fallen in the crises he had investigated. Dr. Allott concluded from his study of the chemical changes in the blood that the syndrome of low sodium and chlorine and high potassium was found in all cases, and that treatment with salt alone did not in all cases restore the blood picture to normal and keep it so. Cortical extract seemed to affect the potassium and urea much more than the sodium and the chlorine. Sometimes there was evidence of blood dilution as revealed by a fall in the serum protein and haemoglobin. Two interesting

cases had been admitted to hospital for quite different conditions. In both of them adrenal insufficiency had been diagnosed by blood chemistry and confirmed by post-mortem examination. One was a woman who had suffered from very severe vomiting which had been regarded as hysterical and not taken seriously until her systolic blood pressure had been found to be 70. She was almost moribund on admission to hospital, although she showed no pigmentation, and had died before any treatment could be instituted. At autopsy her suprarenals had been found to be quite atrophic. The second patient had been diagnosed as cancer of the stomach and had shown the typical blood picture. The only pigmentation he had shown had been a patch over the spine of each scapula. An important point for diagnosis was that in Addison's disease the fall was much more a fall in sodium than in chlorine, whereas in uræmia the fall was more marked on the chloride side than on the sodium side. The typical blood picture was not found in other conditions such as lung abscess, cancer, and hæmochromatosis.

Dr. GRAHAM observed that the really important thing was to obtain a cheap cortical extract. If it were not so expensive at present, no one would think of using salt.

The Vitamin B₁ Content of Human Diet

Dr. AUDREY BAKER read a paper by herself and Dr. Margaret Wright on an estimate of the amount of vitamin B₁ provided in certain standard diets. Cowgill, she said, had made the first estimate of this vitamin by determining the minimum amounts necessary for dogs, pigeons, rats, and mice. He had devised a formula relating the amount to the body-weight and the calorie intake:

$$\frac{\text{Vit}_1}{\text{Cal}_1} = \frac{3.27}{115,000} \cdot W_1$$

It was nowadays possible to make an assay of food-stuffs against the international standard unit, and to get an idea, not only of the beri-beri threshold, but also of the intake necessary for the maintenance of good health. Dr. Baker first of all considered a number of diets which were known to have been associated with outbreaks of beri-beri. When the amount of vitamin B₁ in these diets was worked out, it was found to vary from 71 international units to 382. Over 4000 cases of beri-beri had occurred in a few months in Bilibid prison, Manila, and the diet contained only 71 international units per person per day. The diet in the prison had been improved to 163 units but beri-beri, although reduced, had not been entirely stamped out. On a diet containing 122 units in Java prisons there had been some cases of beri-beri. In an Irish asylum 106 per 1000 of the patients had contracted the disease although their diet contained 438 units; it was, however, thought that the patients had not eaten all that was provided for them. There had been a thousand cases of beri-beri in the Dutch East Indian navy on a diet containing 90 to 180 units; when this was improved so that it contained 253 units it had protected natives but not Europeans. It was clear that no one specific intake protected all individuals; the vitamin allowance must be related to the weight and calorie intake. A diet which would protect from beri-beri might contain anything from 145 to 500 international units per person per day according to the weight and diet.

It was interesting to see what allowance of vitamin B₁ was obtained on various diets which had

been published. Barborcka's skeleton diet had 343 units per person per day. The B.M.A. specimen bare ration gave 212 units on a basis of 3460 calories, but the committee stated that they thought that this diet was deficient in vitamins. The B.M.A. individual diet No. 2, described as typical for the working-man with adequate income and sufficient in vitamins and minerals, yielded 440 units for 3060 calories. Barborcka's typical diet included "cooked cereal" and, according to the cereal selected, gave from 463 to 743 units.

The question of children's needs was a more difficult one. Judging from published diets, a higher level of B₁ was desirable. The B.M.A. diet for a child from 3 to 6 gave 298 units for 2089 calories. Sample diets by Simmonds gave from 376 to 393 for children of this age and from 606 to 657 units for a child of 11. The Ministry of Health's advisory committee on nutrition, in its report on Poor Law children's homes, gave a 2749-calorie diet which yielded 450 units of B₁ per child.

Diets which were definitely stated to be high in vitamin contents gave larger figures. Barborcka's high vitamin diet represented 872 to 1012 units and Simmonds's from 693 units upwards, while the highest of all was that recommended by Theobald for pregnancy toxæmia: 1520 units. Experimental animals showed clearly that more B₁ was needed in pregnancy: three to five times as much as the normal. There was therefore a wide difference between the protective level and a really high vitamin diet. In the intermediate zone the B₁ content of a mixed diet depended on an informed selection of foodstuffs. Such factors in the rejection of food as dislike, indigestibility, economy, or difficulty of preparation might reduce the content below the level of the physiological requirements for health.

ROYAL MEDICAL BENEVOLENT FUND.—The hundredth annual general meeting of the Fund will be held on Tuesday, March 24th, at 5 P.M., at 11, Chandos-street, London, W., when Sir Thomas Barlow, F.R.S., the president, will take the chair.

At a recent meeting of the committee 13 new applicants were helped and 29 grants were renewed. In all £1029 was voted. The following are particulars of a few cases helped.

A. B., aged 77. Retired from practice in 1925. Is now suffering from arthritis and severe sciatica and finds walking difficult. His savings are exhausted and he is living with his married son whose means are only £2 a week. The Fund voted an emergency grant of £5 and a maintenance grant of £40, payable in four instalments.

Widow, aged 36, of M.B. who died last year leaving her and their two children penniless. The widow is to take up training in chiropody and the Fund voted a maintenance grant of £36, payable in four instalments. The Ladies' Guild will help in the educational expenses of the children.

C. D., aged 79, has outlived his savings and finds it extremely difficult to get posts as locum tenens. Fund voted £40, payable in four instalments.

Daughter of doctor, aged 63. Suffering from tuberculous mesenteric glands. Lives in Switzerland for the sake of her health. A grant of £26 was voted by the Fund towards her medical expenses.

The son of a deceased medical practitioner aged 88, who was in receipt of a Fund's annuity till his death this year, writes:

"May I take this opportunity, once more, of thanking the committee for the manner in which my father's annuity from the Fund was administered. It was very largely instrumental in making his closing years comfortable and peaceful."

As this is the centenary year of the Fund a special appeal is being made for new subscribers to carry on the work begun a hundred years ago. Since then over £398,000 has been distributed in charitable allowances. Cheques should be sent to the hon. treasurer of the Fund, 11, Chandos-street, London, W.1.

MEDICAL SOCIETY OF LONDON

At a meeting of this society on March 9th the chair was taken by Sir THOMAS DUNHILL and a paper on

Phlebitis and its Treatment

was read by Mr. A. DICKSON WRIGHT. The terms thrombosis and phlebitis were virtually synonymous, he said, since the former was almost an inevitable result of the latter, while some amount of reactionary phlebitis always accompanied thrombosis. There seemed to be no one special organism or cause associated with phlebitis, and organisms had never been convincingly cultivated from the vein. On the continent there had been an endeavour to class phlebitis as a metabolic disease, caused by cholesterol and treated with light-hearted endocrine cocktail mixtures, often combined with the rather fantastic ritual of Bagnolles spa. Since 99 per cent. of phlebitis was in the legs the one common ætiological factor seemed to be stasis.

Certain forms of phlebitis could be regarded as parts of definite primary disease syndromes. Essential thrombophilia was a rare disease of great gravity with a tendency to affect the arteries as well as the veins. Thrombophlebitis migrans was a febrile disease of long duration occurring in the extremities of persons with low blood pressure. It was not dangerous or disabling and rarely extensive, for only small vessels were involved. When focal sepsis had been removed the patient should go away to a healthy bracing place and not be kept in bed. Ephedrine should be given to raise the blood pressure and enough thyroid to produce a mild toxicosis. Nevertheless every disease had its malignant forms, and in this condition the kidneys might become infarcted and pleuropneumonia might develop. Traumatic phlebitis was the result of injury to superficial veins. It might occur in the axillary and subclavian veins as the result of carrying weights or of injuries through downward snatching. Prognosis in these cases was poor if the cephalic vein could not empty into a patent subclavian vein. If there was associated brachial paralysis the inflamed vein should be dissected out from the nerve bundle. Phlebitis was a usual protective process in the neighbourhood of suppuration but if the clots themselves suppurated the condition became serious. This might be seen in the jugular vein in mastoid disease, the superior mesenteric vein in appendicitis, and the facial veins in carbuncle of the lip. A few cases had followed the injection of contaminated solutions into varicose veins. Proximal ligation was satisfactory and was sometimes combined with evacuation of the suppurating clot. Buerger's disease was an affection of the superficial veins of the leg and eventually of the deep veins also. In time the arteries might show an affection. Mesenteric thrombosis was often due to venous rather than arterial thrombosis and tended to occur in portal obstruction and after removal of the spleen. Familial phlebitis might take any form and post-operative thrombosis and embolism also ran in families.

SECONDARY PHLEBITIS

The vast majority of cases belonged to the secondary group and might follow a medical, obstetrical, or surgical illness. All prolonged prostrating illness was apt to be complicated by phlebitis—e.g., typhoid, pneumonia, influenza, and malaria, in that order of frequency. Rheumatic and typhoid fevers were the only cause of juvenile femoral thrombosis. Coronary

thrombosis was often followed and occasionally preceded by a femoral thrombosis and this condition might also be seen in pregnancy when thrombosis of normal and varicose veins was quite common. The largest number of all forms of secondary phlebitis, however, came under the heading of puerperal. The term phlegmasia alba dolens should be reserved for femoral thrombosis. A solution of this complaint was still awaited. Of the surgical causes, post-operative cases provided the bulk and appendicitis headed the list. Other operations of evil effect were cholecystectomy, hysterectomy, prostatectomy, and gastric procedures. Certain countries had a bad reputation for this disease and operations on the leg veins had a high incidence; no doubt the tourniquet was a fruitful cause. Fractures of the legs and pelvis also produced thrombosis.

Phlebitis in the legs could be classified as superficial and deep vein thrombosis. The latter was the more serious and its appearance was a catastrophe in any case. It was contributed to by changes in the blood—e.g., increased coagulability, increase in blood-platelets, increased viscosity from dehydration, and increased sedimentation-rate; and by retardation of the blood flow due to the position of the patient, increase of abdominal tension or restriction of the respiratory movements. Nothing could be done to return the blood to normal and the injection of anticoagulants was rather disappointing. Much, however, could be done to remove retardation of flow. The Fowler position was bad; it should be maintained with a foot-rest and not a knee pillow and dispensed with as soon as possible. It caused stasis in the veins and the lower limbs. Tight bandaging and meteorism restricted the venous return and peritoneal pain or rigidity of the chest wall restricted respiratory movements. Deep breathing exercises were very valuable. The leg should be examined regularly from the fifth day until getting up, and early sitting out after operation and childbirth had much to recommend it. All precautions should be doubled if there was a personal or family history of phlebitis.

TREATMENT

Posterior tibial phlebitis should be treated by binding the leg with Elastoplast from toes to groin; this sometimes avoided a femoral extension. Femoral thrombosis caused swelling often heralded by low pyrexia and steadily increasing pulse. The pain was sometimes agonising. The patient should be kept horizontal with the leg in a Thomas's splint on a Souttar's beam, and fluid should be given abundantly. Citrate was valueless as, contrary to current belief, a large dose was a powerful coagulating agent. A thyroid high-protein diet was valuable if a definite degree of thyrotoxicosis was produced. Local applications were valueless, but a cooling friction of menthol in methylated spirit was an excellent placebo. Adhesive strapping sometimes enabled the patient to get up as early as the third week and generally before the sixth.

Superficial phlebitis might be simple or ascending. The latter was more vicious and characterised by a good deal of pain, pyrexia, inflammation, and peri-phlebitis. This type of case had provided the few embolic fatalities after injection treatment of varicose veins. Superficial phlebitis was much more often a spontaneous complaint than the deep variety and the main predisposing cause was previous phlebitis. Especially common was inflammation of the collateral varicose veins which developed many years after femoral thrombosis. Focal sepsis should be sought in every case. A large amount of superficial phlebitis

could be prevented by the early and adequate treatment of varicose veins. Superficial phlebitis was an innocuous complaint in an ambulatory subject but had a definite risk when the patient was in bed. Any fluctuant swelling in the veins should be aspirated and then 2 in. strips of adhesive plaster, $\frac{1}{4}$ in. wide with chamfered edges, were stuck over the affected veins at the upper end of the clot and the whole leg bandaged tightly, from the toes to an upper Sorbo safety pad applied above the clot to prevent its wandering upwards. In ascending phlebitis the pressure applied should be greater and the rubber pad of double thickness. Most cases cleared up in a fortnight. In both simple and ascending types the patient must be kept about, even if he had fever. The bandaging prevented embolus. In 500 cases this treatment had always given excellent results. Embolophobia was a real trouble to many patients, and those who found their phlebitis treated thus lightly were most grateful.

DISCUSSION

Dr. A. P. CAWADIAS complained that Mr. Dickson Wright had dwelt too much on the metabolic element of phlebitis. No one on the continent thought that the condition was due to abnormal cholesterol metabolism. The pituitary gland had a certain regulating rôle on the metabolism of the vessels, and patients with phlebitis often had pituitary syndromes. The incidence of phlebitis in families showed, however, that the metabolic element existed and was important. Physicians should search for this element because much of the future therapy of phlebitis depended upon knowledge of it. Physicians and not surgeons saw such conditions as gouty phlebitis. The medical treatment was the same as the treatment of the sequelæ. Preparations of pancreas, pituitary, and parathyroid were not very helpful and endocrine therapy must be designed on the endocrine formula of the individual patient. Physical treatment was most important, especially with infra-red radiation. Balneotherapy had proved useful, and the best drugs were such preparations as hamamelis, hydrastis, and pulsatilla.

Mr. W. MCKIM McCULLAGH said that death-rates from this cause varied greatly in different hospitals. Where deaths were frequent they might be due to improper aseptic technique or improper preparation of the skin. The maternal death-rate from embolism was 6.8 per cent. of the total in England and Wales.

Mr. C. P. G. WAKELEY said that in listening to Sir Bernard Spilsbury's Harveian oration on pulmonary embolism a few years ago, he had been astonished to hear that sepsis played no part. He recalled vividly a patient of his who had been operated on for hernia and had had a femoral thrombosis which had passed up the inferior vena cava. He had suffered from glycosuria which had been taken to be due to thrombosis. This had suddenly ceased and he had recovered. Thrombi could pass up the inferior vena cava and into the heart without killing the patient immediately.

The CHAIRMAN said that one of his problems was the devastating sequel to a simple appendicitis when, just as the patient was about to go home, the surgeon found that phlebitis had set in, there was a pulmonary embolism and the patient sat up and died. One woman, with a successfully operated diaphragmatic hernia, had done this as she was taking her first good meal. Ligation of the large veins above the clot seemed useless. The patients who caused him anxiety were those who came to the out-patient department with a swollen shoulder and a cyanotic arm. They all cleared up in the end but were terrify-

ing in the beginning. He could not believe that all these conditions were due to strain.

Mr. A. C. PALMER remarked that of the 18 cases in his department in 18 months, not all were due to grave conditions; some had followed curettage and one an examination under an anæsthetic. He had come to the conclusion that sepsis played a very minor part and that perhaps the most important factor was slight trauma associated with personal peculiarity.

Dr. MONTAGUE SMITH related a case in which an elderly man had died after an operation for a growth of the sigmoid. There had been no question of sepsis there. He wondered whether patients with a protuberant abdomen and great long veins were more liable. Some work would be necessary in future, on the lines of Mr. Wakeley's remarks, to determine the real cause of the terrible occasional cases of pulmonary embolism.

Dr. A. H. DOUTHEWAITE observed that the main point of the rare condition of thrombophlebitis migrans was the pulmonary complication: the clotting or phlebitis in the small pulmonary veins which caused agonising crushing pain in one side of the chest and complete immobility, but no spitting of sputum or blood. Some femoral thromboses associated with cancer of the stomach were primarily thromboses in the inferior vena cava. He also had been astonished to hear that sepsis played no part. The temperature in these patients never quite settled after the operation, and this was suggestive of sepsis. Physical treatment was important after the operation and every patient, especially after abdominal surgery, should be given massage of the legs or movements and static traction of the thigh muscles 24 hours after the operation.

Mr. C. HOPE CARLTON drew attention to the associated problem of septicæmia, and quoted the case of a Chinese with an enormous carbuncle who had developed basal pleurisy. The acute phlebitis of the penis occasionally seen in prostatic cases was nearly always fatal; he asked for advice on treatment. In some severer cases of femoral thrombosis, especially where bladder drainage was being carried on, it was impossible to get the patient up.

Mr. D. H. PATEY remarked on the difficulty of estimating whether the forms of treatment suggested by Mr. Dickson Wright were of any value since the incidence of pulmonary embolism was so relatively small. He doubted whether deep breathing exercises would make the diaphragm move; some radioscopic observations he had made indicated that they would not.

Mr. DICKSON WRIGHT, in reply, said he thought the good results claimed at Bagnolles probably had a large psychic element. There was no evidence that phlebitis had a pituitary origin and he doubted whether it would ever be shown to be due to endocrine disorder. A patient with an acute suppurative appendix was more likely to get thrombosis after an operation than one with a clean appendix. The immediate cause was probably increased sedimentation-rate. Obesity was an important predisposing cause. Penile thrombosis after prostatectomy was part of an extensive thrombosis which was well known as a sequel of this operation. Draining the bladder need not interfere with getting the patient out of bed for several hours a day. Ligation was only indicated in suppurative phlebitis; varicose veins were ligated to produce thrombosis. Still more foolish was the practice of excising a mass of inflamed varicose veins.

REVIEWS AND NOTICES OF BOOKS

1935 Year Book of Urology

By JOHN H. CUNNINGHAM, M.D., Associate in Genito-Urinary Surgery, Harvard University Post-graduate School of Medicine. Chicago: Year Book Publishers; London: H. K. Lewis and Co., Ltd. 1936. Pp. 462. 9s. 6d.

THERE must be few tasks more difficult to discharge with success than the editing of a volume reviewing advances in a branch of medicine that is growing rapidly. Dr. J. H. Cunningham has shown skill in eliminating papers that, while interesting enough, throw no new light on the problems of urology, and in including in his volume all those which are of real importance. The chief trend of the 1936 volume is thus to concentrate on significant papers and to quote fully from them rather than to attempt to include isolated scraps from a large number. For example, Mr. Swift Joly's Ramon Guiteras lecture on urinary calculus has been reviewed at considerable length as an excellent survey of the aetiology of calculus. The impression left on the reader by this Year Book is that urology, having gained its independence as a speciality in medicine, is now beginning to develop and maintain a close connexion with other branches of medicine during the study of urinary problems. As an example may be given our growing appreciation of the influence of denervation of the adrenals on conditions such as neuro-circulatory asthenia, hyperthyroidism, peptic ulcer, epilepsy, and polyglandular diseases. This new attack upon the adrenal nerve-supply comes within the surgical province of the genito-urinary surgeon, and it is a field of research full of promise. At the same time it is noteworthy how great is the help now being given to urologists by biochemistry, physiology, and endocrinology.

It would not be remarkable if in a Year Book of the literature on any subject edited in America contributions of American workers should receive special prominence; the national bias occurs in every country. So far as it is possible to do so, Dr. Cunningham has avoided undue partiality, and whilst including important papers from every country, has been particularly generous to British writers.

Incompatibility in Prescriptions

Fourth edition. By THOMAS STEPHENSON, D.Sc., Ph.C., F.R.S.E., F.C.S., Editor of the *Prescriber*; sometime Examiner to the Pharmaceutical Society of Great Britain. Edinburgh: The *Prescriber* Offices. 1935. Pp. 62. 6s.

THE medical student has little time to devote to chemistry and pharmacy and it is only when he is qualified that the subject of incompatibility in prescriptions begins to worry him. This book is conveniently planned to enable him to get the necessary information. It deals largely with the chemical and physical aspects of the subject. That the present edition has been thoroughly revised and brought up to date is evidenced by the notes on acetylcholine, acriflavine, benzocaine, calcium gluconate, and hexyl-resorcinol. The classification of the different types of chemical reactions is good and serves to emphasise the principles underlying the subject rather than to provide a mere list of unrelated incompatibles. Much care has been taken in the compilation of the examples. Exception might be

taken to the inclusion of a statement that magnesium sulphate gives a clear solution with sodium bicarbonate without a warning that such a mixture is liable to explode if kept in a well-corked container. A slow evolution of carbon dioxide inevitably occurs and the rate of the reaction is considerably increased with slight rise of temperature. The prescribing together of these two ingredients, particularly in the presence of bismuth carbonate, should thus be avoided. The need for chemically equivalent quantities of potassium iodide and mercuric iodide to produce a precipitate should have been emphasised; in mixtures the iodide is practically always present in excess. A number of interesting examples of therapeutic incompatibility is given and should suffice to warn the prescriber of some pitfalls. The second part of the book consists of a comprehensive dictionary of incompatibles, including many unofficial substances. It is to be regretted that luminal sodium does not appear under its proprietary name in either the list or the index.

The book fulfils its object and can be recommended as a useful addition to the practitioner's books of reference.

Emotions and Bodily Changes

A Survey of Literature on Psychosomatic Inter-relationships, 1910-1933. By H. FLANDERS DUNBAR, M.D., Ph.D., Departments of Medicine and Psychiatry, Columbia University. New York: Columbia University Press; London: Humphrey Milford, Oxford University Press. 1935. Pp. 596. 25s.

WITH medical knowledge, as with the world's food-supply, the problem of distribution is more baffling than that of production. Distribution is greatly facilitated by the volumes of short abstracts, which are becoming increasingly numerous and popular. This one deals with the old question of the relation of body and mind, and attempts to survey and present what has been written on it in the last twenty years. Part I. deals with the problem in general, and with the various physiological methods—precise in form but disappointing in result—which have been suggested for the investigation of its details. Part II., occupying half the book, works through the physiological "systems" of the body and gives examples of their diseases. Part III. is a short section on therapy, and there follows a bibliography of 2251 titles. The abstracts are fairly full, and quotations and excerpts are freely used.

The book is offered in the first place to the would-be research student as a means of orientation and a guide to what has been written. Papers are chosen for abstraction because they are interesting, not because they are necessarily judged to be sound. In merely arranging them the compiler has done a useful service, and in his few paragraphs of introduction and conclusion he has made the dry bones begin to live. His interest is that of the physician more than that of the philosopher. He finds that medical men, following the biologists, are just beginning to study the organism as a whole, its internal relationships and balances, and its interaction with its environment. The antithesis of mind and body in the human organism is giving place to an attempted synthesis; diseases and symptoms are no longer to be labelled organic or functional (meaning, of psychological origin), but in every case the question is to be, "To

what extent organic *and* to what extent functional ?' This point of view is gaining ground in medicine, and promises to throw light on obscure diseases as well as to broaden the service that medicine can give to humanity; for that reason this book, or parts of it, should appeal to workers in many branches of medicine.

I and Me

A Study of the Self. By E. GRAHAM HOWE, M.B., B.S. Lond., D.P.M., Associate Physician, Institute of Medical Psychology; late Chief Assistant, Psychology Department, St. Thomas's Hospital. London: Faber and Faber Ltd. 1935. Pp. 256. 7s. 6d.

Dr. Howe must be congratulated on a brave attempt to solve by a somewhat new dialectical method the ultimate problems of thought and behaviour. He deals with the problem familiar to philosophers of the unity of the self by the proposition that all experience tends to be a relation of twoness. This concept of relation of two terms as the basis of fundamental logical propositions is not, of course, a new one, and the resolution of antitheses has baffled thinkers since the time of Zeno. Dr. Howe applies his theory of unity to such fundamental psychological problems as the family and society and continues his exposition by a critical analysis of science and modern medicine. He accuses unscientific thinkers of idolatry and the competitive faculty which fights for half truths, always forgetting the other pole of an antithesis. Science, he says, is the study of reality as the external, and omits internal conditions in their relationship to externals or appearances. The truth in science and behaviour can only be reached by the resolution of opposites and the path to this realisation ends with the life of the Saints; he gives St. Francis as the shining example. St. Francis, however, was never able to resolve the antinomy of love and hate, though it is true that he had the capacity to accept both. This does not appear to be Dr. Howe's solution, which implies the resolution rather than the acceptance of opposites. Fundamentally his thesis would logically impose upon him an Oriental rather than a Western philosophy, and his ideal should be not so much a St. Francis as Bodhisattva. It is difficult to see what practical application this book could have, but no doubt Dr. Howe in his next volume will apply his philosophy to the actual problems of living.

Objective and Experimental Psychiatry

By D. EWEN CAMERON, M.B., Ch.B. Glasg., D.P.M. Lond., Physician in Charge, Reception Service, Provincial Mental Hospital, Brandon, Man.; formerly Assistant Physician to the Glasgow Royal Mental Hospital. New York: The Macmillan Company; London: Macmillan and Co., Ltd. 1935. Pp. 271. 12s. 6d.

Dr. Cameron opens his work with an apparent paradox by stating that the study of psychiatry needs dehumanising—freeing from anthropomorphism—and that although we are still engaged in the forging of experimental instruments, the ideals for all future lines of inquiry shall be quantitative, verifiable, and repeatable experiments and observations. Medical science like the other sciences must free itself from animism. And furthermore it must pursue the scientific method however much its findings may meet the obstacle of prejudice which is raised when the

higher functions of the mind are subjected to detached scrutiny and analysis. Dr. Cameron holds that we must once and for all abandon the dualism born of the belief in the inviolate soul and in accepting causality and abandoning free will, accept as a fact that human behaviour is predictable and controllable. Admitting the legitimate claims of gestalt and holism, the author believes that the investigation of partial processes by quantitative experiment will tell us what the organism does, if not what it is, and that this should not be summarily dismissed as a sterile study. Dr. Cameron then proceeds to discuss at length the various partial approaches to the study of psychiatry. Particularly interesting is the chapter on tests for intelligence, the subject being approached with commendable reserve. The importance of environment in determining the quality of the highest level reactions is fully recognised. The chapter on conditioned reflexes takes the literature well up to date, but the one on heredity is all too brief. The rest of the book is devoted to recent researches in combined psychiatric and pathological studies.

The volume is well documented chapter by chapter, and should be in the hands of those students of psychiatry who are interested in the experimental approach.

Vitamins in Theory and Practice

By LESLIE J. HARRIS, Sc.D., D.Sc., Nutritional Laboratory, University of Cambridge and Medical Research Council. Cambridge: University Press. 1935. Pp. 240. 8s. 6d.

IN welding his Royal Institution lectures into a book Dr. Harris has given us a popular account of the vitamins which, in a fairly small compass, sets out most of what a layman ought to know about them. The facts are accurately given, though possibly over-simplified in certain places. The abandonment of a dignified style appropriate to scientific literature in favour of a more lively and colloquial one is a doubtful advantage, and not altogether successful here since it seems to involve a definite loss of lucidity. A great many well-chosen illustrations are supplied and the last chapter entitled "Dietetics—What to Eat" is full of interest. It contains some astonishing data on the improvement in nutritional condition of school-children which has taken place in this country since a genuine science of nutrition has grown up. Acquaintance with such facts as these should hearten all who desire to see progress in this direction go still further.

The Obstetric Pelvis

By HERBERT THOMS, M.D., F.A.C.S., Associate Professor of Obstetrics and Gynecology, School of Medicine, Yale University. Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1935. Pp. 115. 11s. 6d.

Dr. Herbert Thoms has discovered many points of interest about the pelvis in the course of his prolonged and considerable experience. Starting with a comparison of the male and female pelvis, he describes in detail the three normal types of female pelvis that he recognises. He notes that the value of external measurements of the pelvis has long been doubted, and gives much space here to a detailed description of X ray technique, with the use of a grid, as a more close means of estimating the real size and shape of the bony birth canal. It

is of interest that so ardent an advocate of exact pelvimetry as Dr. Thoms is constrained to admit that the deciding factor is generally in the end the efficacy of the uterine contractions. He demonstrates that occipito-posterior positions are more likely to be found in women, who have what he calls the anthropoid pelvis. Final chapters deal with injuries and displacements to the sacrococcygeal joint and the symphysis pubis. The book is well illustrated and makes interesting reading, though most of the subject matter is not new.

Agents of Disease and Host Resistance

By FREDERICK P. GAY and associates, past or present members (with four exceptions) of the Department of Bacteriology, College of Physicians and Surgeons, Columbia University, New York. London: Baillière, Tindall and Cox. 1935. Pp. 1581. 45s.

THIS is a large and ambitious work devoted to the ætiology of parasitic diseases in the most general sense. It deals comprehensively and systematically with immunology, bacteriology, epidemiology, proto-

zoology, and helminthology. There are good reasons why these subjects should be treated together in manuals for the elementary student, but there appears no advantage in such an arrangement on a large scale. It is clear that the editor has meant to produce a "treatise" rather than a book of reference. The connecting thread which runs somewhat faintly through the work is the general pathology of ætiology. Dr. Gay has been assisted by many specialists, chosen mostly from the same medical school in order to achieve a homogeneity difficult to secure when wisdom is drawn from a wider field. Each individual article is well written and no labour has been spared in the editorial share. It seems to us unlikely, however, that students will attempt to read such a long and by no means lightly written work with any approach to continuity. Its form, moreover, offers little encouragement to the reader. The book is heavy to hold and has much small print, and rather niggardly margins. As a work of reference it is no doubt of value, though since we have already many good reference books on bacteriology and cognate subjects, it cannot be said to fill a need. It is nevertheless a sound and learned production which may be consulted with advantage by advanced students, teachers, and research workers.

NEW INVENTIONS

SPECIAL CIRCUMCISION FORCEPS

IN the course of running a minor operation clinic at Guy's Hospital where the work is done by dressers of little or no experience, it was evident that the operation for circumcision entailed under these circumstances considerable needless hæmorrhage, and the results were to say the least of it inartistic.

The blind method, where the forceps are applied to the intact foreskin, gives a neat result, but in theory seems to contravene an essential surgical principle that it is as well to see exactly what you are cutting before you cut, and in practice, under the conditions mentioned above, has occasionally been attended with disastrous injury to the glans.

The method of slitting the dorsum of the foreskin, wiping the glans off the adherent foreskin around the whole of its circumference and removing it with scissors under direct vision after ligaturing the frenular artery has been found to be the safest

FIG. 1.—The circumcision forceps.

method, but has resulted in a jagged edge, due to the uncontrolled cut, and hæmorrhage from the remaining arteries until these have been secured.

In order to combine the advantages of the first method with the safety of the second the special circumcision forceps were designed and proved so successful that it was thought their use might profitably be extended to those with more experience.

The foreskin is slit along the dorsum exactly in the midline as far as the corona, this manœuvre being attended by a minimal amount of bleeding. The glans is wiped off and the frenular artery secured. The special forceps are then applied to the foreskin around one-half of its circumference about $\frac{1}{2}$ cm.

FIG. 2.—The instrument in use.

away from the penis as shown in the illustration. The foreskin is pared flush with the instrument and two fine catgut mattress sutures are inserted passing through both mucous membrane and skin between the forceps and the penis. On removal of the forceps there is accurate apposition of skin and mucous membrane and generally no bleeding whatever from the crushed vessels. The instrument is then reversed, the remaining foreskin removed, and two more mattress sutures inserted. A sterile finger bandage soaked in tinct. benzoin co. and applied to the penis completes the operation.

Dressers performing the operation for the first time produce with these forceps a comely effect, take half the time, and succeed in letting blood only to the extent of just staining their fingers, whilst those with a little more experience find it a useful and practical method.

The instrument is manufactured by Down Bros., St. Thomas's-street, London, S.E., and can be supplied in any size.

H. J. B. ATKINS, F.R.C.S. Eng.

THE LANCET

LONDON: SATURDAY, MARCH 14, 1936

INDUSTRIAL PULMONARY DISEASE

THAT the incidence and fatality of silicosis in Great Britain during the last few years is probably much greater than is suggested by the number of notified cases and death certificates is a conclusion that may fairly be drawn from Dr. E. L. MIDDLETON'S Milroy lectures, delivered before the Royal College of Physicians on Feb. 27th and March 3rd. Silicosis is now recognised as the most important of that group of diseases which have been termed collectively the pneumoconioses. In this country it is always the result of prolonged exposure to certain kinds of dust in the course of occupation. The chief symptom is progressive dyspnoea; the chief sign, detectable in life by X rays, is the presence of fibrous nodules in the lungs, which appear post mortem as palpable macroscopic nodules. According to Dr. MIDDLETON recourse to histological examination is usually necessary for diagnosis only in the presence of such complications as tuberculosis—by far the most common one—and malignant disease. He pointed out that the presence of tuberculosis may render the diagnosis very difficult and quotes E. H. KETTLE'S statement¹ that since the differential diagnosis depends on the amount and distribution of the collagen in the tissue reaction, it is a matter of degree.

Silicosis is not reportable, as are certain other occupational diseases, and until a few years ago the term had hardly been used for the purpose of certifying the cause of death in this country. Since the beginning of 1930, by arrangement with the Registrar-General, the Home Office has obtained copies of the certificates of all deaths due to fibrosis of the lungs, silicosis, asbestosis, or pulmonary disease due to dust. Dr. MIDDLETON, from his official appointment, was thus in a position to collect data not previously available. During the five-year period 1930 to 1934 inclusive the number of deaths included in the group was 4038. In 1521 of these silicosis was mentioned on the certificate as a cause of death. The deaths were divided among 29 industries; the figures remain fairly constant for each over the five-year period except for coal-miners, who show a steady increase from 41 in 1930 to 85 in 1934. They head the list with a total of 326 deaths for the five years, the next important groups numerically being those engaged in the manufacture of pottery (270), sandstone masons (255), metal grinders (142), sandstone quarriers and dressers (117), and gold-miners who had returned home from South Africa suffering from the disease (104). Analysis of the 270 pottery deaths showed that the occurrence of silicosis

among potters is always preceded by exposure to flint dust either alone or mixed with clay. The actual number of deaths in each industry has of course less significance than their proportion to the number of workers at risk, but this figure is rarely obtainable. For example, in the census of England and Wales for 1931 the total number of sandblasters amount only to 1395; 17 of them died of silicosis in that year and 45 in the five-year period, giving a mortality-rate of 6.4 per 1000 living, which would be still higher if the census figure did not include shot blasters working on clean metal who are not exposed to siliceous dust. The dust hazard is from the abrasive, usually a quartzose sand or crushed flint, which has now been largely replaced by metal grit or shot. A striking fact which emerges from the investigations on sandblasters is the shortness of the period of employment which led to death from silicosis, compared with other occupations. Another industry, the manufacture of abrasive soaps, was altogether abandoned at one factory in 1928 owing to the death of workers, attributed to inhalation of the dust. Out of a total of 81 persons employed in the process at this factory, 22 left within two months of beginning work, 1 of these dying eight years later of tuberculosis. Of the remaining 59 employed 13 died of tuberculosis or silicosis. In tin-miners the 91 men who died of silicosis in the period under review represent an annual fatality-rate of 11 per 1000 wage-earners employed in the industry in 1934. Hæmatite mining, formerly considered free from risk, is now known to produce silicosis, and during recent years evidence has been accumulating that certain workers employed in coal-mines contract a disabling and even fatal fibrosis of the lung. Dr. MIDDLETON detailed the processes underground in a coal-mine which involve exposure to siliceous dust, and noted that between June, 1931, and December, 1935, the Silicosis Medical Board of the Home Office issued 987 certificates on account of silicosis in coal-mines; these included 237 suspensions, 581 certificates for total disablement, and 169 for death. In these and other occupations in which silicosis, that is, the nodular form of pulmonary fibrosis, occurs, the workers have been exposed to the dust of free (uncombined) silica. There are, however, other industries which involve exposure of workers only to combined silica in the form of silicates. The type of fibrosis produced in the lung by the action of silicates, such as fireclay, sillimanite, china clay, talc, and mica differs from that produced by free silica, and can be distinguished from it by radiological and histological means. The pulmonary symptoms and signs arising from exposure to silicates are generally slight, asbestos dust being unique amongst them for the prevalence and severity of the disease which it causes. During the five-year period 50 deaths were certified as due to asbestosis. In view of the gravity of these scourges it is satisfactory to learn from the annual report of the Medical Research Council, noticed elsewhere in this issue, that their committee on industrial pulmonary disease, appointed at the request of the Home Office in 1930, have now in progress a

¹ Proc. Roy. Soc. Med., 1933, xxvi, Sect. Path. p. 23.

carefully planned and coördinated programme of research. The problem is being attacked from all possible aspects—physical and chemical, experimental and pathological, clinical and statistical—since at present preventive measures are severely hampered by lack of exact knowledge. Silicosis is insidious in its onset, and it is not known how much of the dangerous dust must be inhaled, and over what period, to produce disabling effects. Much also remains to be discovered as to the influence—as regards degree of danger—of the size-distribution and concentration of the dust particles at the time of inhalation. Research into the physical nature of the dust clouds capable of producing disease was accordingly one of the first undertakings of the committee, and this is now being pursued by means of a new form of thermal precipitator devised by H. L. GREEN and H. H. WATSON.² More recently the committee have been considering the need for further study of the chemical properties of dusts arising from industrial processes, such as the composition of the particles and their solubility under different conditions, and this work will be done under the direction of Prof. H. V. A. BRISCOE. Meanwhile, biological investigations on the subject are being continued, notably pathological investigations of material from human cases of industrial pulmonary disease and experiments on the different effects which dusty atmospheres of various kinds have on the lungs of animals. Direct studies of disease in the living subject are also being made as opportunity offers, but the possibilities of making progress in this direction are slight. Most of the symptoms produced are not peculiar to disease owing its origin to dust, and the question thus becomes a statistical one, involving a comparison between the incidence of pulmonary disease among persons exposed to dust inhalation in their occupations and the incidence in the general population; but the task of obtaining records for strictly comparable groups of people, differing only in the one respect of exposure to dust, is beset with serious practical difficulties.

The other side of the problem, which concerns the Home Office rather than the Medical Research Council, involves the arrangements under which victims of industrial pulmonary disease or their dependants can obtain compensation from employers. A memorandum on the Industrial Diseases of Silicosis and Asbestosis issued a year ago³ gives a succinct account of the various schemes providing for compensation and of the medical arrangements for examination and certification of cases. The memorandum states that compensation in cases where death or disablement is caused by silicosis, or silicosis accompanied by tuberculosis, is now payable in all the industries where a serious risk of the disease exists. That the mechanism is not as smooth as might be desired is plain, however, from the periodical complaints in Parliament of which the most recent is reported on p. 632 of this issue. Last month⁴ Mr. LEACH

asked the Home Secretary if he would consider introducing further legislation to ensure prompt and easier certification of cases of silicosis in the mining and quarrying industry, and to ensure that compensation and measures for the recovery of the victims might be made more certain; and, as a supplementary question, whether he did not agree that "both the law and the regulations operate very harshly towards these poor fellows." Sir JOHN SIMON, in his replies, said that he would be happy to consider any suggestion for the improvement of the medical arrangements and the procedure under the Silicosis Schemes, and that he had the fullest sympathy with those who wanted to have the whole situation cleared up and simplified. It is clearly desirable that medical men should familiarise themselves not only with the criteria for the differential diagnosis of the various industrial pulmonary diseases during life but with the present mechanism for obtaining compensation, in order that any remediable defects in it may be exposed and adjusted.

PEPTIC ULCER

Dr. DANIEL DAVIES has done a service in projecting peptic ulcer once more on the screen of public attention and interest, for the real problem of its cause and mechanism is apt to be neglected by those whose first concern is of necessity to treat its symptoms and its complications. His Bradshaw lecture, which appears in our last issue and in this, is a clinical study of 377 cases of chronic peptic ulcer, on the features and fortunes of which he makes some useful observations. He prefaces these by a reference to the experimentalist's success, achieved at last, in producing chronic peptic ulcer in animals. F. C. MANN and his colleagues diverted the bile and the pancreatic juice in dogs into the lower ileum, and half of them developed duodenal ulcers. When the duodenal secretion also was diverted, and the stomach anastomosed directly to the jejunum, jejunal ulcer developed in nearly every animal. The ulcers were histologically just like chronic peptic ulcers in man, and their occurrence at precisely those spots in the intestine on which the acid gastric content impinged points very strongly to the acidity as a prime factor in their causation. Rapidly advancing ulcers could reach the stage of perforation in 48 hours, and three weeks was long enough for the typical appearances of chronic ulcer to develop.

Dr. DAVIES looks for clinical parallels to these phenomena. His figures for gastric acidity illustrate the common finding that in patients with duodenal ulcer the gastric juice is either normal or above normal both in amount and in acid concentration. This is usually regarded as a constitutional trait of the patient. Dr. DAVIES, however, found a number of cases where the acidity appeared to be lower after treatment, and he wonders whether it may not often fluctuate more than is realised. This question is extraordinarily difficult to answer. Even the acid concentration

² Medical Research Council, Special Report Series No. 199, 1935.

³ H.M. Stationery Office, February, 1935, 4d.

⁴ See THE LANCET, March 7th, 1936, p. 576.

measured in the ordinary test-meal, depending as it does on half a dozen or more variables, is not easy to interpret, and no kind of test-meal can be expected to give a very accurate picture of the acidity to which the duodenal mucosa is exposed throughout every 24 hours. HENNING's work¹ on the persistent nocturnal secretion of acid in patients with duodenal ulcer needs emphasis again in this connexion. BLOOMFIELD and POLLAND,² advocating the simple examination of the pure juice secreted in response to histamine are recognising the uncertainties of the test-meal methods, and transferring their attention from what the stomach perhaps does, to what the stomach, maximally stimulated, can do. Their method should help to define some of the determinants of gastric acidity, though it will not give a full answer to Dr. DAVIES's question. Among the gastric ulcer cases his figures show less departure from the normal range than do the duodenal ulcer figures, and in both there is so much overlapping between normal and abnormal groups that the acidity level in any single patient is of very little diagnostic value indeed. There remains, however, the obvious general relation between acid and ulcer, both in man and in the experimental animal, and therein lies at present the justification for alkalis and other antacid measures as a part of ulcer treatment.

Dr. DAVIES's radiological findings bring further evidence that gastric ulcers often heal—or at least go so far on the way to healing that their niches disappear—within a few weeks, and he has some significant examples of the reappearance of craters within similarly short spaces of time. It is quite likely that the ulcer itself, like the ulcer dyspepsia, comes and goes with a mysterious alternation. The problem broadens at once. It is not a single ulcer that is to be dealt with, but a stomach that has developed a habit of ulcerating. Is any gastric mucous membrane capable of behaving like this? No, only subjects with a constitutional proclivity will have ulcers; that is the answer of HURST and those who believe with him in ulcer diatheses. More evidence on this topic is needed, and it would clarify matters greatly if the evidence were presented under two headings such as these. First, there are observations like the occurrence of ulcers in families, from which a constitutional factor may be inferred, but not defined. Secondly, there are observations such as the commonly accepted relationship of high acidity to duodenal ulcer, or DRAPER's anthropometric measurements, which go some way towards defining in anatomical or physiological terms the constitution in question. No diathesis is satisfactorily described until such definition is achieved, and the means by which the constitution invites the disease made clear. But if we grant the existence of an ulcer diathesis as a working hypothesis, we next inquire what sets the stomach ulcerating. Is it a direct infection? No organism has been convicted, but a virus has not been excluded. Is it toxins from

a distant focus or from without? Is it an excess of mechanical or chemical stimulation? More factors than one are likely to be involved and among them Dr. DAVIES stresses the psychological one. In general he thinks the increasing incidence of peptic ulcer may be related to the increasing psychological strain of modern town life; in particular he quotes many examples of the development or recurrence of ulcers following emotional upsets and strain. He pleads, therefore, for "a treatment which is wide enough to envisage the whole man and his environment." It may be more important to lessen anxiety or limit responsibility than to diminish acidity. The weeks in bed insisted on by most régimes for the medical treatment of ulcer usually achieve this, if only incidentally and temporarily. Dr. DAVIES, obliged to treat his patients ambulant, has no doubt dealt with their psychological problems more directly and less short-sightedly, for his results so far as they can be assessed at this stage are not unsatisfactory. He ends with another protest against the hard demarcation of "functional" from organic disease; he is right, and the doctrine needs more preaching, for it is so easy to acquiesce in and so difficult to practise.

THE IMPORTANCE OF GONORRHEA

THE high incidence of gonococcal infections in all civilised communities and the relative failure of measures by public health authorities to check or control their spread are facts which the lay public and most of the medical profession seem to view with indifference. Gonorrhœa is not a spectacular disease. Its emergencies are few and its mortality negligible. Its victims do not make themselves conspicuous. Yet there can be few diseases which bring in their train such misery and wretchedness, so much ill-health and incapacity, so many permanent ill-effects on mind and body. Far more often than not, it affects the young, the strong, the producing section of the community; and its total cost to any nation is beyond computation in terms of public health estimates.

Many factors have combined to negative the efforts which have been made and are being made to cope with this disease. The absence of a specific remedy, the necessity for concealment, the lengthy and dispiriting treatment, family reinfections and inadequate standards of cure, are real bars to progress. But perhaps the lack of inspiration and encouragement to the aspiring investigator—a lack which reflects the popular appraisal of the problem—has done more than anything else to produce what PELOUZE describes as almost twenty years of stagnation of scientific and clinical interest. Recognition of this need for coördination and stimulation of research led to the appointment in the United States in 1932 of a Committee for the Survey of Research on the Gonococcus and Gonococcal Infections. The report of this committee, which is issued as a supplement to the January number of the *American Journal of Syphilis, Gonorrhœa and Venereal Diseases*, reflects great credit upon the assiduity and

¹Henning, N., Norpoth, L.: Arch. f. Verdauungskr., 1933, liii., 64.
²Jour. Amer. Med. Assoc., 1929, xcii., 1508.

discrimination of those concerned in its preparation, and will be found directly valuable by all who have to treat gonococcal infections. The nature and the magnitude of the problem is indicated by the estimate that in the United States alone there are a million cases a year. The committee's contribution towards a solution consists in the first place of a statement of the biology of the gonococcus, presenting the known and accepted facts with a critical summary of what has been written on the subject in the past five or six years. Some 50 further pages are devoted to the results of research into gonococcal infection in man, and here the compilers are able to maintain the same keenly critical attitude—except occasionally, and naturally, in relation to the investigations of workers with whom they are in close contact. Finally the report contains a summary, a discussion, conclusions, and suggestions for future developments. A study of the document as a whole must convince the reader that its authors are right when they deplore the confusion of thought over these problems, the lack of unanimity on fundamentals, and the fact that conclusions are often drawn and defended on wholly inadequate

grounds. They also note that there is much wasteful overlapping of effort by research workers, and where, as often, this is due to their being out of touch with current publications, the present report will do much to remedy the deficiency. Financial and other facilities are held to be insufficient, and it is remarked that many who receive an adequate preliminary training in this type of work pass on, through force of circumstances and often through no wish of their own, to other spheres of labour. The committee thinks it probable that less than ten centres in the whole of the United States are engaged in serious study of gonorrhœa.

Few will deny that these criticisms and conclusions are equally applicable to the state of affairs in this country, and it is to be hoped that signs of awakening interest abroad may lead to a more general realisation of the importance of the problem here. The encouragement, coördination, and financing of inquiries into cancer have become a national concern, backed by the interest and support of the medical profession and all classes of the community. Is it too much to expect that some comparable attention may be given to the urgent demands of the gonococcal infections?

ANNOTATIONS

THE RADIOLOGIST'S PROPERTY IN HIS NEGATIVES

THE British Institute of Radiology has found it necessary to make a pronouncement as to the property in radiographic negatives of private patients. It states with authority and confidence that the property is in the radiologist by whom, or under whose instructions, or in whose department, the negative is made. The statement is applicable also to hospitals where arrangements permit the visiting radiologist to receive and examine private and paying patients; the hospital receives a proportionate part of the radiologist's fee towards the cost of materials used. In the case of hospitals this problem of property can be highly important because insurance companies and solicitors are sometimes inclined to demand as of right the visible results of the radiologist's work. Sometimes also patients raise the same question. If disposed to dispute liability for fees, they have been known to argue that there is nothing to pay for if the negatives have not been handed over. When that argument was used last year in an American case, the Supreme Court of Michigan disposed of it very sensibly. Radiographic negatives, said the judges, were practically meaningless to the layman; they were an important part of the doctor's clinical records, valuable to his professional experience; they were analogous to the microscopical slides which doctors prepare as an aid to diagnosis and treatment and which would hardly be said to belong to anybody but to the doctor who prepares them.

Patients unfortunately are apt to think of themselves as visiting the radiologist to have an X ray photograph taken just as they go to a professional photographer's studio for their portraits. In the latter case, where the sitter pays for the portrait, the copyright is in the sitter though the legal property in the negative remains in the photographer, though part of the bargain may be that the photographer is not at liberty to sell copies or to use the

negative without the sitter's authority. That was the decision in *Boucas v. Cooke* in 1903, where Cooke, the "boy preacher," had his photograph taken (for payment) in order that a block might be made for reproducing his portrait for distribution at missionary meetings. The analogy of portraiture is shown by the British Institute of Radiology to be misleading. Patients do not visit a radiologist in order to purchase a picture of their bones, nor should they be encouraged in any such idea. The radiologist makes his examination in order to reach an opinion about the patient's condition; the radiogram is merely incidental to the formation of that opinion; indeed it may happen that an opinion can be formed from screen examination alone and, if so, the radiologist's fee is none the less payable.

HISTORICAL ASPECTS OF PSYCHOLOGY

IN the paper he read at the Royal Society of Medicine last week Prof. Millais Culpin pointed out that the history of psychological medicine had not been one of steady progress since the eighteenth century. Stahl, for example, had propounded his valuable conceptions, in many ways akin to those which now hold the field, but his views had not influenced the course of medical opinion about neurosis during the succeeding two centuries. Within the last fifty years great changes had taken place. The artefacts of Charcot's clinic in France could be paralleled in their own time by the outbreak of "railway spine" in this country; the medical attitude to both was influenced by the notion of purely physical causes and by an aversion from teleological interpretation. In spite of the refutation of Charcot's teaching about hysteria by Bernheim, and the researches of Janet, Morton Prince, and the psycho-analysts, it was not until the outburst of psychogenic disorders in the late war that a psychological approach to hysteria and other neuroses began to prevail over the neuronic and molecular explanation of their pathology. Freud's views were those of a pioneer and a genius, but, looked at

historically, they seemed to have been put forward on to a scene that was set for them; a dynamic psychology, working in part with the conception of unconscious mental activity, had been adumbrated by various physicians and philosophers, and the situation was not unlike what had occurred earlier at moments of vicissitude in the history of psychological medicine. Unduly simple interpretations, whether in terms of conditioned reflexes or endocrine glands, were to be met with succeeding each other now, just as Haller's "irritability of nerves" had followed van Helmont's *Archæus*, at the time when Stahl was proffering vainly a more adequate explanation of the part played by states of mind and total dispositions in causing mental and physical disease.

The discussion which followed Dr. Culpin's address ranged from the therapy at Epidaurus to the claims of modern psychopathology. The members of the section of history of medicine were evidently agreed that in psychiatry, as in every other branch of medicine, a true and wide picture of the present state of our knowledge could not be obtained unless one paid heed to the historical background. It is, however, a common observation, as in the case of Freud to which Prof. Culpin drew attention, that innovators and men of genius are often without a full knowledge of earlier and contemporary work in their field. Such ignorance may be a source of strength; it enables them to follow new lights, undeflected. This argument is not entirely at variance, however, with the orthodox one so strongly urged in the discussion. Few are called to be innovators of ideas, and even men of genius are much influenced by the work and ideas that prevail in their time or have preceded them.¹ Other recent writers² on Dr. Culpin's theme have pointed out how regularly psychological medicine has followed the fashions and philosophies of the period; unwitting assumptions are made, current belief is mistaken for assured fact, and familiar general modes of thought are woven into the new structure. The influence of Nietzsche, to which Dr. Cawadias referred, has doubtless played a part in moulding the psychological theories of to-day; a more detached historical view than that possible to the psychopathologist might discern in his accepted tenets of the moment much that derives from biological and philosophical habits of thought which are now being superseded or reshaped.

A STUDY OF HYPERNEPHROMA

In introducing his monograph Prof. P. Bull makes a modest disclaimer. It contains, he says, "no original ideas on the pathogenesis of hypernephromata, no unknown pathological-anatomical discoveries, nor any new clinical observations. . . . The work is primarily written for my Norwegian colleagues. . . . As it has been my lot to treat a comparatively large number of hypernephromata, I have felt it as a kind of duty to give an account of my own clinical experiences during more than twenty years." The monograph was subsidised by the Malthe Fund and is published as a supplement to the *Norsk Magazin for Lægevidenskaben* for January. That 37 cases of hypernephroma of the kidney may be seen in a score of years by a general surgeon, not limiting his

activities to the urinary tract, is an indication that the condition must not be considered altogether rare. Of the 37 patients 21 were males, and three-quarters of the total were between the ages of 40 and 59. Hæmaturia was the first symptom in about a third, while in another third hæmaturia plus pain were the first manifestations. Only about half the patients showed macroscopic hæmaturia when they came to hospital, and 8 did not even show microscopic hæmaturia on admission. Pyuria was demonstrable in only every sixth case. It will thus be seen that the routine laboratory examination of the urine is apt to be defective as an aid to diagnosis. Pigmentation of the skin was observed only in 1 case, but among the 21 males no less than 5 suffered from varicocele. Pyelography provided convincing evidence of a new growth in 18 out of the 21 cases thus examined, and Bull thinks that hæmaturia traceable to the kidneys, but otherwise of doubtful origin, should be an absolute indication for pyelography. In all, 26 of the 37 patients underwent nephrectomy, which in 20 cases was extraperitoneal and in 6 transperitoneal. The ultimate results justify operation, although it was not always successful in preventing recurrence. All the 5 cases with thrombosis of the renal vein or vena cava ended in this way; but, on the other hand, the prognosis when the lymphatic glands about the renal vessels showed metastases proved not absolutely hopeless.

SURVIVAL IN PULMONARY TUBERCULOSIS

By careful inquiry into the after-histories of patients treated at sanatoria, various attempts have been made to assess the success attending the treatment of patients with pulmonary tuberculosis. One of the more extensive surveys was made by Sir Percival Horton-Smith Hartley, R. C. Wingfield, and J. H. R. Thompson¹ and related to the patients treated at the Brompton Hospital Sanatorium at Frimley during the years 1905-14. Since 1924, when the report of this survey was published, the After-History Records Department at the hospital has functioned continuously, and functioned so successfully that rather less than 8 per cent. of the patients have been lost sight of. The material available for analysis has consequently become very considerable, amounting to 8766 patients admitted to the sanatorium between 1905 and 1931. The records of these patients—largely representative of the classes of insured persons of the London area—have been made the subject of a valuable report by Horton-Smith Hartley, Wingfield, and V. A. Burrows.² The numbers involved have made it possible to study the after-histories of patients of each sex separately, of different age-groups, and of different grades of severity. For the last the classification suggested by the Ministry of Health in Memo. 37/T has been adopted—namely, Grade A, patients T.B. minus, and Grade B, patients T.B. plus, divided into three groups of increasing severity. For each of these groups the mortality experience has been computed, the figure adopted for comparison being the probability of surviving five years after the date of admission to the sanatorium and at the expiration of each succeeding year. Against these probabilities are placed the corresponding figures from English Life Table No. 9, which was based upon the deaths of 1921-23.

Examination of the figures shows that the mortality

² The Expectation of Survival in Pulmonary Tuberculosis, Brompton Hospital Reports, vol. iv., 1935.

of these patients depends almost entirely on the stage of the disease at entry and is relatively unaffected by sex or age. The prognosis varies directly with the extent of lung involved, though the authors point out that striking individual exceptions are often encountered. The prognosis of the average case unfortunately does not appear to have changed materially during the past thirty years, for the patients of more recent years show after-histories very similar to those of cases treated in the earlier years of the period studied. On the other hand it seems that for a selected class—namely, patients treated by artificial pneumothorax—modern treatment has considerably improved the prognosis. The majority of patients chosen for this treatment belonged to the class B3—i.e., with little or no prospect of recovery—because in the majority of cases this treatment was not used until the usual routine treatment had proved ineffectual. Comparison of this group with the experience of all the remaining patients of the same sex, medical grade, and age at admission shows a probability of survival materially increased in those so treated, the benefit enduring for at least 12 years. This method of comparison appears to be the best available but it inevitably leaves the reader wondering why if two patients are really equal in all relevant characteristics one is chosen for A.P.T. and another not; does some unrecognised or immeasurable factor lead to the discrimination and is this factor correlated with survival? A fundamental factor in the prognosis of the pneumothorax cases is shown to be the freedom from disease of the contralateral lung. Presumably the control group did not differ in the frequency with which this characteristic was present. An important feature of the authors' tables is the high mortality in the second and third years after admission to the sanatorium. This, as they point out, may be due in part to the fact that it may be several months before the disease terminates in death, but it also emphasises the well-known fact that the most perilous year for a patient suffering from tuberculosis is the year following his discharge. He has then to face conditions of living and occupation and may relax that "careful watchfulness over his general routine of life" which no sufferer from pulmonary tuberculosis can ever afford to neglect however secure his health may appear.

A special analysis has been made of the distribution of deaths over the calendar year, and it is found that the monthly variability is greater for deaths of the Frimley patients than it is for the deaths from pulmonary tuberculosis recorded in the general population but less than the variability of other causes of death in the general population. This intermediate position of the Frimley patients points, the authors argue, to the conclusion that the mortality experience of patients who have had sanatorium treatment is more favourable than that of members of the general population suffering from pulmonary tuberculosis. The argument is not very clear. If a relatively high monthly variability of deaths can be taken as evidence of increased vitality then it would seem that the comparison needed is between ex-sanatorium patients and other patients with pulmonary tuberculosis, both groups dying of *any cause*. The comparison of ex-sanatorium patients dying of any cause with other patients dying only of pulmonary tuberculosis *must* give a greater variability to the former, since tuberculosis has less seasonal variability than many other causes of death. The authors' belief that this statistical evidence is the first to show the value of sanatorium

treatment needs, we think, careful consideration. From their final conclusion no observer of tuberculosis patients is likely to differ. They conclude that in the majority of cases "two stages may be observed—the first symptomless, the second symptom-producing; that for this reason all too frequently patients with early disease fail to seek advice; that modern methods of treatment can only improve the prognosis where the disease is not too extensive, so that the patient can fall into a selected category; that he is unlikely to fall into this class, unless the disease can be detected during its symptomless stage. This must be the goal of clinical research if further progress is to be made." The perfection and more general use of radiology during the last ten years, encouraging earlier diagnosis and more accurate control of treatment, may well show a beneficial effect when, as is to be hoped, this admirable investigation is extended in another ten years' time.

NERVOUS COMPLICATIONS AFTER SPINAL ANALGESIA

THE possibility of damage to the central nervous system from endothelial injection has been a subject of controversy since the early days of spinal analgesia. There have always been some who maintained that nervous sequelæ were numerous and serious; others who asserted the opposite. The former, it must be admitted, could rarely bring definite evidence in support of their belief and were apt to fall back on the statement that "neurologists saw many cases of trouble after spinal injections." Gradually knowledge is becoming more definite and it appears that the risk of damage from endothelial injection must be accepted as a real one, although it is at present quite impossible to estimate how its frequency compares with the frequency of undesirable symptoms after inhalation anaesthesia. Nor is it possible to compare the comparative frequency of really serious sequelæ after the two methods. For such comparisons we need parallel series of cases embracing very large numbers, and even then unless the operations and the conditions of the patients in the two series were substantially similar the comparison would be of little value. The kind of damage which may follow spinal analgesia is well shown in a recent article¹ from New York which is of value because of the full description of the cases, seven in number, and of the microscopic post-mortem evidence in one of them. The authors give no indication of the number of cases among which these seven occurred, so that our knowledge of the frequency of damage is not furthered by the article in question. It would appear that a meningitis, of non-septic nature, is not an uncommon sequel of spinal injection. This is recovered from rapidly, but when the nerve-roots, and still more the cord itself, are affected the trouble is more serious and may be permanent. Paralysis arising in this way is exemplified in one of the seven cases quoted by the American authors and H. K. Ashworth cited² a similar instance. Dr. Ashworth stated that minor symptoms or lesions after spinal injection were not infrequent and often persisted, although he believed serious or dangerous sequelæ to be rare. His investigation of patients with post-operative nervous symptoms showed the importance of a thorough examination, several instances being found where symptoms demonstrably due to some other cause had been attributed to the

² Proc. Roy. Soc. Med., 1933, cxxvi., 501.

spinal injection. Endothelial analgesia is so valuable a method, and in some circumstances so superior to all others, that it is very important for its risks to be understood and every possible means taken to obviate them. Besides the patent necessity for strict surgical cleanliness there is need for care both in the method of making the injection and in the choice of dosage. With regard to the last point it is to be noted that the doses of procaine used in the New York cases were in several instances much above those commonly injected in this country.

ALCOHOL IN HOSPITAL PRACTICE

Dr. Courtenay Weeks has collected some interesting statistics showing the decline in the use of alcohol in hospital practice from 1900 to 1934.¹ In 1934 the hospitals of the British Empire spent, on an average, only 3.8*d.* per patient on wines and spirits. Most of the hospitals in the London area spent more than the average. St. George's, for example, spent 20.4*d.* per head and this far from convivial figure shows a decline of 4*d.* compared with the figure for 1923. In the provincial general hospitals the decline was equally marked. Exceptions, murky or glittering as you will, were the Margate Royal Sea-Bathing (28.5*d.*) and the West Kent (22.8*d.*). In Ireland, the Tyrone County Hospital spent 22.4*d.* per head and the Dublin Meath 18.2*d.* Nor does Scotland stand where she did. Only the Oban (W. Highland Cott.) and the Johnstone and District Hospitals spent more than a shilling a head. Except for the Merthyr General Hospital (25.3*d.*), the Welsh hospitals were all below the average. Of public assistance institutions, the Bristol-Southmead Municipal Hospital spent 22.6*d.* and the Dartford (Kent) 19.7*d.* The L.C.C. General, the Women's and Children's Hospitals, and the sanatoria all returned low figures. Bootle (Linacre) was the only hospital for infectious diseases to return a figure as high as 19.3*d.* English mental hospitals (4.8*d.*) were markedly more abstemious than either Scottish (11*d.*) or Irish (16.5*d.*). All hospitals of the Empire overseas returned low figures and the same is true of the European countries though many French hospitals freely prescribe "Potion de Todd," a strongly alcoholic carminative. Dr. Weeks's object in collecting these statistics is to preach the cause of temperance. He claims that they prove that the profession no longer believes in the therapeutic value of alcohol. No doubt his claim is partly true, but other factors, for example, the increased cost of alcoholic liquors, must also be responsible for their diminished use. The propaganda which accompanies the statistical data may prove tedious to some readers. Had Dr. Weeks contented himself with a plain statement of facts he might perhaps have carried greater conviction.

ACUTE POISONING FROM CORROSIVE SUBLIMATE

MERCURY bichloride is, after arsenic, the commonest metallic poison responsible for acute poisoning. The intention is most commonly suicidal, but many accidental cases are on record. As little as grs. 3 has been fatal, but much larger doses have been taken with survival. The poison always causes intense vomiting, so that most of it is generally eliminated within a few minutes. The vomiting is usually persistent and is soon accompanied by profound purgation. Occasionally death occurs within a

few hours from collapse following the intense dehydration and dechloridation. More commonly death takes place in 5 to 10 days from uræmia, and in these there is anuria, generalised œdema, and very high blood-urea. There is, however, a paucity or absence of published data on the quantitative elimination of the metal during life and on its distribution in the organs after death. These data must necessarily be of fundamental importance in guiding treatment, and recent chemical studies by Sollmann and Schreiber¹ are accordingly of considerable interest and value. Their material was derived from four patients seen during life and three autopsies, and a very large number of careful analyses were made. These showed that immediate gastric lavage is important, but that subsequent lavage of stomach or colon is of little effect. The first gastric lavage should be very thoroughly carried out and many pints of water used for the washing. The fæces are the principal vehicle for the excretion of the metal, and enemas were thus of value only if the patient had not had the usual diarrhœa, for copious colon irrigations yielded negligible quantities of mercury in the non-fæcal washings. In their autopsy studies Sollmann and Schreiber found that the concentration of mercury is uniformly highest in the kidneys; the liver follows with about half to two-thirds of the concentration in the kidneys; then the spleen with one-seventh, the intestines with one-ninth, the heart, skeletal muscle, and lungs, with about one-fifteenth; and finally the brain with one-twenty-seventh. The concentration of mercury in the blood was 0.015-0.12 mg. per 100 c.cm., about one-fortieth of that in the kidneys. It seems rational to combat the early loss of water and chlorides through vomiting by giving continuous intravenous saline by the drip method. At the same time great caution should be exercised to avoid waterlogging in view of the probability of renal damage. The control of the quantity of saline administered by the usual criterion of the volume of urine passed is obviously unsafe as there may be suppression of urinary excretion.

PRURITUS AND LEUCOPLAKIA

PRURITUS vulvæ, with or without pruritus ani, is one of the most distressing and intractable of all the commoner affections of the skin and adjacent mucous membrane. There are grounds, moreover, for thinking that its incidence is increasing, and the paper by Dr. Elizabeth Hunt which we publish on p. 592 will be useful both for its careful analysis of causation and for its suggestions about treatment. In a longer treatise which has just appeared elsewhere² she has analysed in detail no less than 73 cases of lichen planus of the vulva, which she believes to be often confused with leucoplakia vulvæ—a much more serious affection in that it not infrequently terminates in epithelioma, which the former never does. This contention, which she supports on clinical and microscopical grounds, may safely be left to the examination of her dermatological readers; but she is undoubtedly right in saying that the diagnosis of leucoplakia vulvæ—like the diagnosis of leukoplakia in the mouth—is used too loosely by the profession generally. Nevertheless we might err in caution if we went the whole way with Dr. Hunt. We very much doubt if she will obtain credence for her findings that out of 300 cases of pruritus vulvæ no less than 105 (i.e., over a third) were due to, or associated with, lichen planus. This is certainly not

¹ Alcohol in Hospital Practice. By Courtenay C. Weeks, M.R.C.S., L.R.C.P., Director and Medical Lecturer, the National Temperance League. London: National Temperance League, 1935. Pp. 35. 9*d.*

² Brit. Jour. Derm. and Syph., February, 1936, p. 53.

the ordinary experience of dermatologists either in this country or abroad, and we take leave further to doubt her claim, or that of any other physician, to be able to establish the cause with certainty in 297 out of 300 cases of a disorder which is one of the most puzzling of cutaneous syndromes. Many clinicians may also find it difficult to believe that only one case of ringworm was present in so large a series, and they may be further perplexed by the omission of a menopausal or endocrine variety of pruritus which is widely recognised as common. In other respects, however, Dr. Hunt will find sympathetic support for her views. There is certainly an undesirable tendency to resort to surgical remedies, which are rarely successful and mostly mutilating. With the exception of nerve section, they should be reserved for cases of a frankly malignant type, or those regarded as pre-malignant on microscopical examination. On the medical side, too, there is probably far too much prescribing of local and general sedatives. Not a few of these unfortunate women have become chronic morphine addicts, and it should not be forgotten that cocaine and its substitutes soon lose their anæsthetic properties and sometimes become an important factor in the protraction of the disease.

INVESTIGATION OF URTICARIA

FASHIONS pass; booms turn into depressions. And less is nowadays heard of wild hopes that "allergy" will prove to be the solution of most of the remaining problems of medicine. To force an allergic explanation upon an obscure disorder will often make it retreat further into obscurity. At the same time there are few more fascinating diseases than those which are generally interpreted in terms of sensitisation—for example, urticaria—and there must be revelations about them waiting for us round a corner. At present we are mainly at the stage of observation and experiment, the one often leading to the other. Thus the discovery of sensitisation to chloramine causing spasmodic rhinorrhœa, urticaria, and eczema has led Salén¹ to test the chloramine sensitiveness not only of this particular patient, but also of a number of other veterinary students. To explain the positive skin reactions he found in many showing no clinical manifestation of sensitiveness he concludes that this may be a process normally evoked in most people by adequate exposure to an antigen. The clinical manifestations of such sensitisation may only occur, however, in those with an inherited predisposition to such reactions. In other words, a positive skin test and presumed sensitisation merely indicate adequate contact and do not imply liability to allergic reactions. It does indeed look as though some such explanation must be invoked to explain the unreliability of cutaneous tests, but it is possible that some unrecognised factor in the local mechanism of the test reactions, quite independent of general considerations, is responsible for these inconsistencies. In practice we can no longer suppose that every case of urticaria will be elucidated by conscientious skin-testing against all possible inhaled, ingested, or contact allergens, and the patient's problem has still to be viewed upon a broad medical basis. Particularly in cases of simple factitious urticaria, in urticaria following exertion, and in that provoked by exposure to cold is it difficult to determine the ætiology and institute rational therapy. Thus Levine,² who has lately given a full report of a case of urticaria due to cold, has been unable to draw any positive

conclusions about ætiology; and it seems doubtful whether the state is any more than an exaggeration of the normal physiological response.

LEPROSY IN THE EMPIRE

LAST Tuesday's meeting at the India Office produced many striking statements from the principal speakers. As chairman of executive of the British Empire Leprosy Relief Association¹ Sir Edward Gait said that the number of lepers in the Empire was now put at at least two million. Sir Leonard Rogers, F.R.S., spoke of his belief that if infection in childhood could be prevented the disease would almost die out within a couple of generations, and the same argument was brought out by Dr. E. Muir, formerly of the Calcutta School of Medicine, who has succeeded Dr. Thomas Cochrane as the Association's medical secretary. Leprosy, he said, like tuberculosis belongs to a certain stage in the life-history of a nation. Here in England we rose above that level in the fourteenth and fifteenth centuries, just as we are now gradually rising above the rather higher level of tuberculosis. The campaign against leprosy among backward races must have in its forefront the amelioration of their social and economic conditions. The problem was largely a child problem because children are more prone than adults to infection and develop an active form which spreads infection. So far there was no specific remedy, though "we have a form of treatment which under favourable circumstances will heal the less virulent cases." Compulsory isolation of infectious cases would never succeed among vast uneducated populations, for it drove the disease underground. But, as in many other departments of medicine and social science, much could at once be accomplished if we would only put into effective use the knowledge already acquired. The chief difficulty, in Dr. Muir's opinion, is the ignorance and indifference of people at home. In this country we are at present secure against many of the diseases which ravage our colonies and dependencies, and "with this feeling of security people have very little idea of the difficulties and problems with which governments, missionaries, and others are struggling in those distant lands for which we have taken upon us the responsibility." Funds would pour in, as Sir Leonard Rogers said, if leprosy were as prevalent in Europe now as it was five hundred years ago:

ON March 17th and 19th at 5 P.M. Dr. John Parkinson will deliver the Lumleian lectures to the Royal College of Physicians of London, his subject being enlargement of the heart. Medical practitioners will be admitted on presentation of their card.

OUR news columns this week contain an advance notice of the Second International Congress of the Scientific and Social Campaign against Cancer, which is to be held in Brussels next September, under the auspices of the International Union against Cancer.

Sir Gowland Hopkins, O.M., professor of biochemistry at Cambridge, has been appointed to the faculty of Harvard University for the academic year beginning next September and will deliver three lectures in the Harvard medical school as Edward K. Dunham annual lecturer. The Dunham foundation is designed to promote understanding between students and investigators in the United States and other countries.

PROGNOSIS

A Series of Signed Articles contributed by invitation

XCII.—PROGNOSIS IN CARCINOMA OF THE COLON

THE precision of diagnosis by a competent observer using adequate radiological equipment is now such that no carcinoma of the colon submitted to examination by X rays can escape detection. Its site and outline can be demonstrated, and the mobility of the affected segment of colon can be determined. The demonstration is simple when suspicion of the presence of a carcinoma has been aroused, but unfortunately the absence of symptoms in the early stages of most cases of malignant disease of the large bowel makes diagnosis dependent on obstruction. The cases in which a diagnosis is reached before obstruction has occurred are limited to those in which a growth is found in the course of an operation or an X ray examination initiated for the correction or detection of some other disease.

Study of the natural history of carcinoma of the colon shows that from one to two years elapse between the first appearance of the growth and the first attack of obstruction. During that period of progressive diminution in the calibre of the bowel, the mechanism of compensatory hypertrophy of its muscular coat is so efficient that the patient may and frequently does feel no impairment of his normal health sufficient to take him to his doctor. But during this clinically silent period of growth, metastasis to lymph glands often curtails the prospects of survival. Prognosis after removal of a carcinoma from any part of the body is conditioned chiefly by the presence or absence of metastasis at the time of operation, and this principle is as rigidly determined for the colon as for the breast.

TYPE OF GROWTH

The common pathological type of carcinoma in the large bowel is a localised growth of scirrhous habit, which spreads slowly round the circumference of the gut to form a ring stricture. It affects chiefly the left half of the colon and produces an obstruction which often antedates metastasis by a sufficient margin to make radical removal successful, as success is estimated in the surgery of malignant disease. In the right half of the colon, carcinoma tends to be more bulky than in the left half and to be less rapid in the destruction of its host. The bulky tumour which fungates into the lumen of the bowel is often characterised by so much ulceration and sloughing of its mucous surface that an adequate though irregular passage for the intestinal contents is maintained. On account of this tendency to ulceration and of the fluid nature of the content of the proximal colon, the onset of obstruction may be delayed and the first symptoms to attract the patient's attention may be weakness caused by loss of blood and toxic absorption from the ulcerating surface, or pain associated with infiltration of surrounding tissues by the tumour. Examination of the abdomen at this stage of the disease may reveal a palpable tumour, but if the carcinoma is situated in the hepatic flexure it may be so concealed by the lower ribs and the liver as to escape detection. This point is illustrated by the frequency with which carcinoma of the hepatic flexure remains unsuspected until perforation compels investigation. The splenic flexure, being higher than the hepatic, is even less accessible to palpation, but its characteristic pathological type

of carcinoma is the ring stricture and, as a clinically recognisable obstruction usually antedates glandular metastasis, the outlook for the patient is considerably better. The most favourable type of carcinoma of the colon is the one which produces obstruction at an early stage of its development, whether because it grows at the ileo-colic junction where the lumen is narrow or because its polypoid shape provides an adequate stimulus to the formation of an intussusception.

SITE

The influence of the anatomical site of an operable carcinoma of the colon on prognosis is forcibly demonstrated by the ease with which resection can be performed in those parts of the bowel which are provided with a mesentery. Removal of a growth of a transverse or of the pelvic colon is much simpler than is resection of the fixed parts of the colon, whether the patient's condition allows of primary reconstitution of the continuity of the bowel or necessitates a two-stage operation of the Paul type. Provided that the removal be adequate, the easier the operation the lower the mortality.

SYMPTOMS AND SIGNS

The value to the patient of an attack of acute obstruction, lasting perhaps for 48 hours, at a relatively early stage in the evolution of his disease can scarcely be over-estimated; nor can the value of recognition by his doctor of the potential significance of such an incident in a middle-aged man or woman. The second attack may not come for several months, during which the growth will progress and may spread to lymph glands, and during which the general health will deteriorate as the result of toxic absorption from the chronically obstructed bowel. Wasting is seldom a feature of the disease. Obesity is probably as common among the subjects of carcinoma of the colon as among healthy people of the same age. It increases the risk of operation, not only because the stout often tolerate severe abdominal operations badly, but also because of the technical difficulties imposed by a short, fat-loaded mesocolon.

In the absence of demonstrable metastases, a rational prognosis can only be founded on the data provided by exploration of the abdomen. When the operation is performed in the absence of acute obstruction there will have been ample opportunity for a complete investigation beforehand. The exact site, approximate local extent and mobility of the growth will be known, so that those precious commodities, time and manipulation, can be devoted to the constructive phases of the operation where absence or limitation of metastasis encourages removal of the growth.

IMMEDIATE RISK OF A RESECTION

In assessing the immediate risk of a resection the preoperative preparation of the patient must be allotted a value comparable with our estimate of the adequacy of his cardiovascular and respiratory mechanism, and of his renal sufficiency. Preparation for operation should include not only attention to the alimentary canal but also the raising of the hæmoglobin content of the blood by the necessary number of transfusions to at least 80 per cent. Only in the most favourable circumstances can the patient expect to escape with a single operation, and in the practice of many surgeons the possibility is limited

to growths of the right half of the colon from the cæcum to the middle of the transverse colon. Even then a temporary opening to prevent a rise of gaseous pressure within the bowel is often advisable. In other cases, more than one operation will usually be required in the interests of safety, a short circuit or colostomy preceding the removal of the tumour. A third operation may be necessary to close the colostomy.

IMMEDIATE OUTLOOK IN ACUTE OBSTRUCTION

The immediate outlook for a patient who is first seen in a state of absolute intestinal obstruction depends on such general factors as age and preceding physical condition, and on the number of days during which obstruction has been absolute. When the growth is in the ascending colon the clinical picture is often dominated by the participation of the small intestine and vomiting may be severe, but with obstruction of the more distal parts of the colon distension is the chief feature and vomiting is late and capricious in its incidence. The pulse-rate may rise scarcely at all for the first four days. Within these limits an attack of obstruction does little to jeopardise the success of the ultimate resection provided that the bowel on the proximal side is drained for an adequate time before removal of the growth is attempted. In this connexion it is necessary to recognise that a cæcostomy cannot be relied upon to drain the colon distal to the hepatic flexure, and that Paul's operation, where suitable, is by far the safest way out of an attack of obstruction.

REMOTE PROGNOSIS

A prognosis founded on the relative completeness of a resection must take into account the information afforded by naked-eye and microscopic examination of the tissues removed. The length of colon on either side of the growth is always ample provided that its mucous membrane is healthy, but mere length can only guarantee a margin beyond the zone of submucous infiltration, and if polypi are found on the mucous membrane it is likely that others will have been left in the patient and these will carry a slight but definite risk of malignant change. Of far greater importance is the presence or absence of growth in the lymph glands which will have been removed in continuity with the resected bowel. These glands may be enlarged either by growth or by inflammatory changes resulting from absorption of infection from a malignant ulcer. If, on microscopic examination, they are found to contain deposits of carcinoma, the expectation of life will be greatly diminished.

An operation which achieves adequate removal of the carcinoma as judged by the standards of the pathologist may be expected to yield from four to eight years of freedom from recurrence, growths of the right half of the colon giving a more favourable outlook than those of the left half. On account of the damage produced by an attack of obstruction and the greater liability to post-operative complications which it involves, and by reason of the number and often the severity of the necessary operations, restoration to health is usually slow. Full vigour may be regained or the patient may be hampered by minor degrees of obstruction caused by adhesions.

RECURRENCE

Recurrence is limited to the abdominal cavity and produces intestinal obstruction or enlargement of the liver. These two clinical features may coincide and either may be accompanied by ascites. When

recurrence takes the form of intestinal obstruction accompanied by gradually increasing distension of the abdomen and by the presence of palpable masses, it is unlikely that further operation will be justified either by prolongation of life or by relief of suffering. The problem presented by recurrence of intestinal obstruction without a palpable abdominal tumour or with a single lump, especially if this is localised to the pelvis, demands a fresh investigation by the same methods as in the case of the primary tumour. Prognosis is again dependent on the pathological conditions found at operation. A single recurrent growth in either small or large bowel or in one or both ovaries with an adherent coil of intestine may be amenable to excision with a prospect of two or three years of useful life. In less favourable cases a short circuit or a colostomy may prolong life and reduce suffering for several months, though the patient is unlikely to regain more than a relative degree of health and activity.

E. K. MARTIN, M.S., F.R.C.S.,
Surgeon, University College Hospital.

OUR issue of August 10th contained the last of the articles collected in book form and issued as "Prognosis," Vol. I. (10s. 6d.). The subjects dealt with week by week in this series since that date are as follows:—

Congenital Stenosis of the Pylorus, by Miss Gertrude Herzfeld and Dr. H. L. Wallace. Fractures of the Bodies of the Vertebrae, by Mr. H. Ernest Griffiths. Malocclusion of the Teeth, by Mr. A. T. Pitts. Fibroids, by Mr. Victor Bonney. Jejunal Ulcer, by Dr. R. P. Picton Davies. Foreign Bodies in the Air and Upper Food Passages, by Mr. V. E. Negus. Papilloma of the Bladder, by Mr. Cyril A. R. Nitch. Cerebro-spinal Fever, by Dr. C. Worster-Drought. Non-malignant Diseases of the Breast, by Mr. Eric Pearce Gould. Tetanus, by Dr. Leslie Cole. Gastric and Duodenal Ulcer, by Dr. J. J. Conybeare. Middle-ear Suppuration, by Mr. Walter Howarth. Caesarean Section, by Mr. Eardley Holland. Ulcerative Colitis, by Dr. A. F. Hurst. Internal Derangement of the Knee-joint, by Mr. R. C. Elmslie. Pituitary Tumours, by Mr. Hugh Cairns. Malignant Growths of the Testicle, by Mr. Kenneth M. Walker. Tuberculous Infections of the Skin, by Dr. Henry C. Semon. Trigeminal Tic, by Dr. Wilfred Harris. Chronic Bronchitis and Emphysema, by Dr. R. A. Young. Deafness, by Mr. Harold Barwell. Asthma, by Prof. L. J. Witts. Hemiplegia in Middle Life, by Dr. Neill Hobhouse. Fractures of the Upper End of the Femur, by Mr. George F. Stebbing. Enlargement of the Spleen, by Dr. J. W. McNee. Congenital Syphilis, by Dr. David Nabarro. Spinal Caries, by Sir Henry Gauvain.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—Hospitals situated within 11 miles of St. Paul's which want to participate in the grants made by this Fund for the year 1936 should apply before March 31st to the hon. secretaries of the Fund at 10, Old Jewry, E.C.2. Applications will also be considered from convalescent homes which are situated within the above area or which, being situated outside, take a large proportion of patients from London.

GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL.—At the annual meeting of contributors and subscribers to this hospital it was pointed out that increasing use was being made of the antenatal department. During the past year, 1600 cases, or 35 per cent. of all those admitted to the hospital, attended the antenatal dispensary, the total attendances being 16,572. No fewer than 68 per cent. of the total admissions were abnormal, and the need for extending a part of the hospital was being felt.

SPECIAL ARTICLES

MEDICAL RESEARCH COUNCIL
ANNUAL REPORT FOR 1934-35

THE Introduction to the report of the Medical Research Council provides year by year in 30 brief pages an index, a record, and a forecast: an index to the trend of medical research during the period under review; a record of results achieved to the date of its close; and a forecast, often already confirmed in the intervening six months, of the conclusions reached as the outcome of work essentially complete but not yet published. It is a peculiar merit of this annual report to steer between the policy, unfair to other workers in the same field, of staking out claims for discoveries of which full details are not available and that of supplying a mere summary of communications already familiar to the readers of scientific periodicals.

This year a dozen subjects from among those on which work has been actively pursued are selected for review. Pride of place is given to

Nutrition: Application of Modern Knowledge

There have been many recent indications of greater public interest in nutrition. Though this interest may have been aroused not solely nor even primarily because of the intrinsic practical importance of proper feeding in its relation to health, but largely because of the probable economic effects on agriculture and industry, the Council express satisfaction that the discoveries of their own and other investigators of nutritional problems are likely in the near future to play their due part in advancing human welfare.

HISTORICAL SURVEY

In view of this change in attitude they enumerate some of the more practical discoveries which they have assisted during the 20 years of their existence.

In the first year of their work they initiated research on rickets which led to the elucidation of its nutritional aetiology, and in particular to the discovery of a calcifying vitamin (vitamin D), a substance which was ultimately prepared in its pure form by workers at the National Institute for Medical Research. They also promoted, in association with the Lister Institute, clinical investigations on rachitic children at Vienna, which confirmed the laboratory investigations and placed the methods for the prevention and cure of the disease on a firm basis. Later they supported work, arising from the rickets investigations, as a result of which it is now practicable to improve greatly the structure of the teeth of the rising generation by proper feeding in infancy and childhood. They are also responsible for the clinical investigations which demonstrated that, apart from dental structure, decay of the teeth can be slowed down by diet. This work has led to a new outlook on what is probably the commonest disability of civilised man—namely, dental decay—and has supplied facts ready and feasible for widespread translation into practice.

One of the most important practical investigations initiated by the Council demonstrated the effects of supplementing the diet of growing children with milk and other substances. Through their Accessory Food Factors Committee the Council have initiated and financially supported investigations made with the object of standardising the different vitamins. Vitamin D was first standardised in this country, and the whole series of investigations later made it possible for international conferences, convened by the Health Organisation of the League of Nations in 1931 and 1934, to establish international standards and units for vitamins A, B₁, C, and D. Thus people throughout the world can now discuss these

vitamins in terms of units, in the same way as they can discuss time and distance in units of hours and metres.

Other inquiries supported by the Council called attention to the high incidence and significance of anæmia both in pregnant and lactating women and in their infants in this country, and showed how the condition could be avoided or mitigated. Certain nutritional investigations have been directed to the study of goitre, and others have had as their object the determination and close analysis of the usual dietaries of different sections of the community.

These are only a few of the more important contributions to knowledge in nutrition for which the Council have been responsible. Throughout their existence they have realised the fundamental importance of this rapidly developing subject, and have placed it in the foreground of their programme.

THE NEW TEACHINGS

It is fortunate that the essential teachings can be reduced to a few simple statements. The first is that the younger the child the more essential is correct feeding for proper growth and health. It is thus necessary to apply the new teachings of nutrition to the case of the pregnant and lactating mother; and, despite the great importance of improvement in the dietary of school-children, proper feeding of the infant and child of pre-school age is an even greater need. Breast feeding is of even higher value than has been previously believed, and ought to be more extensively adopted and continued for longer periods.

On the dietary side, the broad requirements can be simply stated to the public—without mention of calories, vitamins, or other technicalities necessary to the investigator—by saying that much more milk ("safe" milk), cheese, butter, eggs (especially egg-yolk), and vegetables (especially green vegetables) ought to be consumed. In particular, milk ought to be the chief drink for children, and especially in the first years, while bread and other cereals should in these early years be greatly reduced.

CURRENT WORK

Prof. E. P. Cathcart and Mrs. A. M. T. Murray have completed the analysis of data on family diets collected from various towns in Great Britain over a period of years, particular attention being given to the iron, calcium, and phosphorus contents of the diets. A quantitative survey of the diets of crofters and others in remote Highland areas is contemplated for purposes of comparison.

A quantitative study of the ordinary diets of 120 men and women has been completed by Miss E. M. Widdowson, working under Dr. R. A. McCance, who with Dr. L. R. B. Shackleton has also continued his observations on the chemical composition of fruits and vegetables and their losses in cooking. It appears that most of the iron of vegetables and bread, and little of the iron of meat are utilised in human nutrition, and that about half the phosphorus of cereals, nuts, and pulses is in a form which cannot be absorbed.

Prof. S. J. Cowell has done further experiments on the factors controlling the excretion of calcium in the intestine. It appears that the rate of excretion depends on the degree of saturation of the tissues generally with calcium, but that it is not much affected by sudden variations in the calcium content of the blood. Miss E. M. Hume, assisted by Mrs. I. Smedley MacLean, D.Sc., have made further observations on the effects of fat deficiency which were noted by Burr and Burr in rats. Experiments are

in progress to determine what substances in lard and linseed oil are responsible for curing the lesions produced and for restoring the rate of growth to normal. An inquiry is also being made into the influence of the fats in the diet on reproduction. Under the general direction of Prof. W. W. C. Topley and Prof. Cathcart, Dr. Marion Watson has obtained preliminary results which indicate that diet and various environmental factors have specific effects on the fertility, growth, and survival-rates of young mice. Attempts are now being made to determine whether it is possible by dietetic means to increase the resistance to *Bact. aertrycke*.

Dr. Helen Mackay is examining the value of a soya bean preparation as a supplement to milk in the diet of infants. The iron content of the bean is comparatively high, and it is thought that it may possibly replace inorganic iron salts for the prevention and treatment of nutritional anæmia. An inquiry at the North Eastern Hospital, Tottenham, showed that the addition of extra rations of vitamins A and D to the diets of children with measles was without effect on the course of this disease or on the incidence of the minor skin infections.

The method devised by Mr. C. O. Harvey to measure minute quantities of iodine in biological substances has been used by Miss M. G. Crabtree to study the iodine content of samples of milk, pasture, and drinking water from different parts of England with the idea of obtaining definite proof whether the incidence of goitre in certain districts is actually related to the iodine-content of the local milk and water supplies. The findings so far indicate that the iodine-content of milk from the non-goitrous districts of Suffolk is higher than of that from the goitrous districts of Somerset.

VITAMIN STUDIES

The seven pages devoted to vitamin studies in this year's report record much work on various components of the vitamin-B complex, and on vitamin C (ascorbic acid) with short sections on the chemistry of vitamin E and notes on the storage and on the standardisation of vitamin A.

As part of an inquiry into the vitamin B₁ content of human diets Mr. P. C. Leong has measured the amounts of this vitamin present in genuine wholemeal wheat and in ordinary brown bread and has found the difference between them to be surprisingly small. By arrangement with physicians at several hospitals trials are being made of the therapeutic effects of vitamin-B concentrates in "pink disease" in children; encouraging results have been obtained in a few cases, although caution is required in their interpretation.

Application of the work of Mr. L. J. Harris, Sc.D., and Mr. S. N. Ray, Ph.D., on the diagnosis of vitamin-C deficiency to children under the care of Prof. L. G. Parsons and of Dr. E. Pritchard suggests that a suboptimal intake of vitamin C is common in artificially fed infants but not in breast-fed ones, human milk being three or four times richer in this vitamin than cow's milk. Observations on adults by Dr. M. A. Abbasy and Dr. Harris indicate that one or two oranges a day suffice rapidly to bring reserves of vitamin C up to normal in persons whose diet has been deficient in this respect, but there is evidence that mothers often disobey instructions to give orange juice regularly to their infants.

The only mention of work on vitamin D in this section of the report is on that of Miss Fischmann, who is studying its influence on ossification in tissue cultures. Elsewhere (p. 137) reference is made to the observations of Prof. J. B. Duguid, assisted by Dr. M. R. P. Williams, on the experimental production of a form of nephritis by giving large quantities of orthophosphates by mouth, in the presence of hypervitaminosis D; and (p. 110) to the study by Dr. Dorothy Russell of the vascular, renal, and pituitary changes found in this condition.

Examples of Combined Clinical and Laboratory Research

Ergot in childbirth: isolation of ergometrine.—The end of the fascinating story, extending over 30 years, of the struggle to reconcile clinical and pharmacological experience in respect to the activity of various preparations and derivatives of ergot is here recalled.

Again and again, during this period, new constituents have been isolated from ergot which, although of great physiological interest, failed to replace in the confidence of the practising doctor the watery extracts of the whole drug. He continued to rely, for the purpose of stimulating contractions of the uterus, on these extracts given by the mouth, though he was assured that they contained none of the alkaloids found to be pharmacologically active when injected. This discrepancy between clinical practice and pharmacological evidence lasted till 1932 when Dr. Chassar Moir was able to demonstrate by objective records the powerful contractions of the human uterus induced by the popular watery extract of ergot. Close co-operation between the late Mr. W. H. Dudley, D.Sc., working on the chemical side, and Dr. Moir enabled them jointly to announce in March, 1935, the discovery of ergometrine as the substance in ergot responsible for the most familiar of the actions of ergot.

The Council point out that these researches, while illustrating how results of equal or even greater importance may be attained by the laboratory as by-products of the chase, also illustrate how vital to the solution of a problem, originating in and concerning clinical practice, may be the guidance provided by continued investigation upon the clinical material itself.

The curative agent of pernicious anæmia.—Another example of the need for continuous clinical guidance is in the testing of the therapeutic activity of preparations derived from liver. It is as yet impossible to foretell whether any particular preparation will be active until it has been tested on patients suffering from pernicious anæmia. No effective laboratory test of activity has yet been established, in spite of world-wide endeavours, while the chemical complexity of the liver principle has prevented the discovery of any chemical or physical property which can be regarded as a measure of its therapeutic influence. The Council were able to organise last year clinical trials by Prof. Stanley Davidson, Prof. E. J. Wayne, and Dr. C. C. Ungley of a preparation of liver extract made by a British firm according to the method of Dakin and West, published in America; the result of these trials (published in *THE LANCET*, Feb. 15th, 1936, p. 349) demonstrated the extremely high degree of potency of this preparation. Injections of from 0.1 to 0.2 gramme of it once weekly, brought about a large increase in the red blood corpuscles of the patients tested and in the course of a few weeks restored them to health.

Prevention of child-bed fever.—Here also the combination of clinical and laboratory research has been effective.

The fact that the morbid agent known to be responsible for puerperal sepsis is a streptococcus characterised by ability to hæmolyse red blood corpuscles has of recent years been supplemented by the knowledge that the cocci having this property comprise several groups and sub-groups, of which only certain members are harmful to human beings. It emerges moreover that the hæmolytic streptococci occasionally found in the genital tract of healthy parturient women are not, as was formerly supposed, identical with those causing puerperal fever, which latter come from some outside source. Dr. Dova Colebrooke has recently tracked down the probable sources of infection. She has confirmed the view that the strep-

tococci of the respiratory tract bear an intimate relation to puerperal fever; and her results suggest that the respiratory tract of the mother must be taken into account as well as that of her attendants, and that familial sources of infection may also be looked for.

Arising from her work is the lesson that it is dangerous for any person suffering from an acute infection of this tract to engage in maternity work, and that maternity and surgical cases should not be treated under the same roof unless the nursing staffs can be kept separate.

Standards for sex hormones.—Under this heading the Council urge medical men using sex hormones in their work to insist on knowing the exact nature and strength of the preparations supplied. The market is flooded with different preparations, and each manufacturing firm has given a proprietary name to its own particular product. While some of these proprietary preparations are good, both their composition and activity being controlled, others are of a semi-bogus nature. The situation lent itself both to quackery and to ignorant treatment of disease until last year a conference, convened by the Permanent Standards Committee of the Health Section of the League of Nations, met in London under the chairmanship of Sir Henry Dale, and made important decisions in respect of nomenclature and standardisation.

A uniform scientific nomenclature and standard units have been adopted for three important natural substances of which therapeutic preparations are now available. These are: (1) "œstrone," "œstriol," and "œstradiol," the œstrus-producing hormones (the alternative names applying to hydroxy-ketonic, trihydroxy and dihydroxy preparations, respectively); (2) "progesterone," the hormone of the corpus luteum which produces in the female the changes associated with pregnancy and pseudo-pregnancy; and (3) "androsterone," a chemical substance closely related to that responsible for the development of the secondary sex characteristics in the male.

The effectiveness of the proposals must ultimately depend on the attitude of those who use the substances. The Council point out that clinical knowledge of the actions of these sex hormones is still very elementary, and it is certain that they are physiologically potent, often in unexpected directions.

Miscellaneous Inquiries.—Travelling Fellowships

Other studies reviewed editorially by the Council are the researches into the value, effects, and possible dangers of different methods of producing anaesthesia; the artificial cultivation of living tissues; iodine and thyroid disease; industrial pulmonary disease; bed-bug infestation and the toxicity of industrial solvents. We shall have occasion from time to time to comment on some of these and on work in progress at the National Institute for Medical Research, at the clinical research units, and under the external research schemes subsidised by the Council.

Regret is expressed that in consequence of a change in policy of the Rockefeller Foundation, the system of international fellowships is being abandoned in favour of concentration upon a more restricted programme for the promotion of research. The Council had been privileged to award five or six whole-time fellowships every year, of the value of between £350 and £450 each; analyses showed that of the 70 men and women who had completed their tenure of these fellowships 12 are professors, 36 others are engaged full-time, and a further 16 half-time in higher teaching and research. The organisation of a new scheme of the same kind is thus

considered highly desirable. A start has been made in the establishment of one such fellowship by the trustees of the late Lord Leverhulme, and the Council suggest that other potential benefactors have here a great opportunity of performing an important national service.

Mr. Ramsay MacDonald, who as Lord President introduces this year the report of the Committee for Medical Research of the Privy Council, announces that the grant-in-aid provided by Parliament for the expenditure of the Medical Research Council last year amounted to £165,000, compared with £139,000 in each of the three previous years. The increase has made it possible to proceed with plans for new research work which had been temporarily in abeyance and to undertake additional investigations required for the purposes of administrative departments. Prof. J. A. Ryle and Prof. Matthew Stewart have replaced respectively Lord Dawson of Penn and Prof. A. E. Boycott as members of the Council, and the impending retirement of the chairman, Lord Linlithgow on his appointment as Viceroy of India is announced with warm appreciation of his services.

MEDICINE AND THE LAW

A Fatal Dose of Paraldehyde

IN *Strangways-Lesmere v. Clayton and others* Mr. Justice Horridge has refused to hold a district hospital at Weymouth liable for the negligence of its nurses. The negligence consisted of administering 6 ounces of paraldehyde to the plaintiff's wife before an operation in mistake for 6 drachms. The honorary surgeon to the hospital gave instructions to the house surgeon for the patient to have per rectum 6 drachms in 9 ounces of water. The night nurse made a pencilled note of the instructions on the bed-board and handed it to Nurse A when the latter came on duty. The judge accepted the evidence of the day sister and the night sister that this pencilled note, thrown away after the operation, specified 6 drachms and not 6 ounces. It was the duty of Nurse A to administer the drug and of Nurse B to check the quantity. The bottle of paraldehyde was taken from a locked cupboard; the label stated that the dose was $\frac{1}{2}$ to 2 fluid drachms. Nurse A poured out 6 ounces (half the bottle) and mixed it with 9 ounces of water; Nurse B watched her do so. The patient died of heart failure due to an overdose of paraldehyde. Mr. Strangways-Lesmere sued the general committee and trustees of the Weymouth District Hospital and also Nurses A and B. He contended that a hospital was, like any other employer, liable for the negligence of its servants. The test was the power of the governors of the hospital to control the nurses' work. A hospital authority was, he contended, protected in respect of the negligence of its nurses only where the negligence occurred in the course of work demanding professional nursing skill over the performance of which the governing body could have no control whatever. Here, said the plaintiff, the hospital authority had clearly assumed control over the measuring and checking of dangerous drugs by nurses because a hospital regulation had been made which required the sister on duty to check the dose. This regulation appeared not to have been properly published to the staff; it was not known to Nurse A or Nurse B; no precautions had been taken to see that the rule was carried out. On the other hand the hospital authorities argued that their

relationship to the nurses was not that of master and servant when the nurses were preparing patients for operations; the nurses were really carrying out the orders of the surgeon in mixing, checking, and administering the drug—which was work demanding professional training and skill. This argument, based on the well-known decision in *Hillyer v. St. Bartholomew's Hospital*, succeeded. Mr. Justice Horridge agreed that the administration of paraldehyde was a skilled operation: it was true that there was a practice at the hospital that all the administration of dangerous drugs should be checked, but he did not think the hospital authorities undertook to administer the doses themselves: the nurses, in giving the doses, were doing their own work as skilled nurses and not as servants of the hospital authority. The administration of paraldehyde, as in this case, was not a matter of a nurse's routine but one in which a nurse had to use professional skill. It was not work which Nurse A was put in the place of the hospital authorities to do, or work which the authorities intended to do for themselves. The only legal duty on the hospital authorities was to see that the nurses whom they engaged were duly qualified persons. The judge was asked to say that, as there was a practice of the hospital to have the doses of dangerous drugs checked, therefore the hospital was at fault in not putting up a printed notice to that effect. He found, however, no evidence that other hospitals exhibited such notices; the evidence was that checking was a well-known practice in hospitals and that the practice was in operation in the Weymouth Hospital. It followed that no negligence had been established against the hospital, and judgment with costs was given in the hospital's favour.

THE NURSES' LIABILITY

The higher the work of nurses is reckoned as an expert professional performance, the more vulnerable they become in the law courts as a separate target. In the Weymouth case the judge found that there was negligence on the part of Nurse A and Nurse B; the damages had been agreed at £100 (if liability should be established), and judgment was given for this amount with costs against the two nurses. The judge said they would have been negligent even if the night sister had herself made the mistake of writing "6 ounces" on the pencilled note. Nurse A had looked at the bed-card and, if she had been careful, she must have seen that the dose was there stated to be "6 drachms." Both Nurse A and Nurse B ought to have looked at the bed-card in measuring out the dose: in that case they would have seen that it was 6 drachms and not 6 ounces. Nurse A was also negligent because the label on the bottle of paraldehyde gave the ordinary dose by the mouth as $\frac{1}{2}$ to 2 fluid drachms and she admitted that she knew that, when administered per rectum, the quantity would be at the most three times the quantity administered by the mouth, whereas the dose she actually administered was considerably larger than that. It had been argued on behalf of Nurse A that the case was unusual. In 99 cases out of 100 the patient's bed-card should be the nurse's Bible, but here the bed-card was inaccurate in no less than three particulars, and the house surgeon had given instructions which were at variance with the directions on the bed-card. As she had received instructions from the night sister, it could not be said that Nurse A was negligent in not following the bed-card. This argument was largely based on the assumption that the night sister made the mistake of writing "6 ounces" in her pencilled note. As

already stated, the judge rejected this assumption and held the two nurses liable.

SYMBOLS OR METRIC SYSTEM

In the Weymouth Hospital case it was supposed that the nurses had confused the drachm-symbol for the ounce-symbol. A medical witness, invited to explain these signs to the court, said that one had "one twist at the top" and the other had "two twists." Counsel dramatically observed that a human life may depend upon the extra twist. The possibility of error has naturally revived discussion of the advantage of the metric system over the traditional mysteries of the apothecary's script. The *New English Dictionary* shows "oz." to have been adopted from the Italian "oz" or "ōz," a fifteenth-century abbreviation: the line above the letters is the familiar sign of a contraction, the full word being *onza* or in the plural *onze*. In Italian manuscript forms of the abbreviation the letter z had a full tail below and the tail was usually carried in a circle under, round, and over the o so as to form the line of contraction above it. It must also be remembered that the symbol ʒ signified the omission of a final syllable, so that oʒ would mean ounce or ounces. It is said that, when printing was introduced, the ʒ became a z to suit the convenience of a limited fount of type, and that, before this change became general, the symbol oʒ had been slurred by hasty writing into ʒ and the lower weight of the drachma was adapted therefrom as ʒ , with "one twist" instead of two (see *THE LANCET*, 1906, ii., 453). In discussing the *British Pharmacopœia* of 1914 (*THE LANCET*, 1914, ii., 907), reference was made to certain recommendations that the old apothecaries' symbols should be abandoned. The symbol ʒj , it was pointed out, may be used to represent 60 grains and also to represent the fluid drachm; the symbol ʒij to represent 480 grains, sometimes 437.5 grains, and also to represent the fluid ounce. Tradition in the writing of prescriptions, however, dies hard. Nor is that surprising in view of the replies to the question: "Is the metric system used in teaching?" put by the General Medical Council to the teaching bodies in 1929. Four of the London and seven other medical schools gave a frank "no"; the remaining replies were little more than a qualified "no." Liverpool had tried the metric system but discontinued it as the students preferred the imperial. The Aberdeen reply is perhaps the most significant: "Sufficient instruction given to enable students to prescribe in the metric system, but they are told that it offers no advantages as regards safety." If the metric system were in use, human fallibility is such that the decimal point might be inserted in the wrong place with serious results. In the Weymouth case the judge elicited the fact that any competent nurse should be able to distinguish one symbol from another.

Societies Charitable and Uncharitable

In the current number of the *Fight Against Disease* the hon. treasurer of the Research Defence Society writes on the menace to hospitals of "antivivisection" methods and finance. He cites a passage from the *Abolitionist* (the journal of the British Union for the Abolition of Vivisection) which comments on a recent bequest of legacies to the Bristol General Hospital and the Bristol Royal Infirmary on condition that "no experiments on living animals have been carried out in the premises for a period of five years prior to the date of actual payment." The *Abolitionist* observes that the Bristol Royal Infirmary is No. 39

on the list of places registered for vivisection under the 1876 Act, and presumes that the legacy will be withheld; "it would be well," it adds, "if it became customary to bequeath legacies with this condition." This comment naturally moves the treasurer of the Research Defence Society to remark upon the persistent attempts of antivivisectionist bodies to divert subscriptions from hospitals merely because the hospital necessarily includes on its staff a pathologist licensed to conduct inoculation experiments for diagnostic purposes, on which the early and efficient treatment of patients depends. Such propaganda may reasonably be described as uncharitable—an epithet which invites re-examination of the technical legal classification of antivivisection societies as charities.

Lawyers are aware of a doctrine known as the rule against perpetuities. Ordinary gifts are void if they infringe that rule. The law, however, has more kindness for charities than dislike for perpetuities. Gifts to a charity do not fail even if they exceed the period of time within which ordinary gifts must take effect. Hence it is important to know whether the objects of the gift are, in the eye of the law, charitable or not. The courts have regarded all objects as charitable which are either expressly named in a now repealed statute of Elizabeth or which are deemed to be by analogy within its spirit and meaning. There are plenty of decisions which show that societies for the prevention of cruelty to animals are "charitable." There is at least one decision, *In re Foveaux*, where antivivisectionist objects were held charitable. Mrs. Frances Foveaux left money to her daughter Catherine with a special power of appointing a fund in favour of charity. The daughter by her will appointed legacies of £300 each to three named antivivisection societies, and Mr. Justice Chitty had, in 1895, to say whether the legacies were valid. He began by refusing to enter into, or pronounce any opinion on, the merits of the controversy between the supporters and opponents of the practice of vivisection. The court, he said, stood neutral. Stated broadly, the one side held that the practice, under careful safeguards, although it might inflict some suffering on the lower order of animals, was justifiable and tended to promote the welfare of the human race and also of the lower order of animals in general. This side had in its favour the Act of 1876 under which the Home Office issues licences. On the other hand, said the judge, the antivivisectionists held that the practice was wholly unjustifiable; it was cruel and immoral. He followed the previous decisions which favoured societies for prevention of cruelty to animals. Accepting the principle that all cruelty is degrading, he held that, if a society for preventing cruelty to animals is charitable, then a society for preventing a particular form of cruelty to animals must also be charitable. He was careful to guard against saying that mere infliction of pain was necessarily cruelty; infliction of justifiable pain might not be cruelty. He wound up his judgment by saying that the antivivisection societies with which the case was concerned might be near the borderline, but he thought they were charities.

The Foveaux case has long been followed, but in 1929 its value was a little shaken in the Grove-Grady will case. Here a bequest to found the "Beaumont Animal Benevolent Society," with provisions for a sort of sanctuary where all wild creatures would live free from human interference, was upheld by Mr. Justice Romer as a valid charitable trust. On appeal a strong argument to the contrary was

built up by Mr. Wilfrid Greene, now a Lord Justice. Mr. Greene contended, amongst other things, that, if the court were not satisfied that propaganda and expenditure for the suppression of vivisection were beneficial to the community, they could not be the subject of a charitable trust. The Court of Appeal (Lawrence, L.J., dissenting) held that a trust in perpetuity for animals might be good if in its execution there was necessarily involved a benefit for the community; if no such element were present, the trust would be bad. Lord Justice Russell, one of the majority judges, said he knew of no decision upholding such a trust in favour of animals on any other ground than that the execution of the trust (in the manner defined by the creator of the trust) must produce some benefit to mankind. "I cannot help feeling," he went on, "that in some instances matters have been stretched in favour of charities almost to bursting point." He thought the authorities had reached the farthest admissible point of benevolence to charities in favour of animals; for his part, he was not prepared to go any further. The cases had run to fine distinctions, and, speaking for himself, he doubted whether some of the former decisions would not nowadays go the other way. "For instance, antivivisection societies, which were held to be charities by Chitty, J., in *In re Foveaux* and were described by him as near the borderline, might possibly, in the light of later knowledge in regard to the benefits accruing to mankind from vivisection, be held not to be charitable." Lord Justice Russell referred later to the *Wedgwood* case where a trust in favour of animals was upheld in 1915. He observed that it was not a decision that every trust for the benefit of animals would necessarily involve the benefit of the community, or that a trust for the benefit of animals which involved no benefit to the community would be a charitable trust.

Undoubtedly the law adjusts itself to changes in public feeling and general knowledge. The Chitty judgment in the Foveaux case pointed out that the medieval "dole" charities were no longer to be regarded as beneficial; they tended to pauperise a district and the court might nowadays find itself against them. Old beliefs change. The antivivisection ideas of past generations, still provocatively propagated by the societies, refuse to allow that any experiment on animals can be beneficial. Lord Justice Russell, in the passage already cited, assumes without hesitation the benefits accruing to mankind from vivisection. The recent failure of the Battersea General Hospital, while maintained on uncompromisingly antivivisectionist lines, is further evidence of the change. The hospital frankly admitted that the restrictions prevented it from giving medical treatment in accordance with the best modern standards. It was even confessed that the staff had been infringing the restrictions in the interests of the patients. The antivivisectionist societies still stand for a policy which attacks what is now recognised as beneficial to the community. To this extent their own objects are the reverse of beneficial to the community and will cease to be charitable, in the legal sense, as soon as the courts follow the direction suggested by Lord Justice Russell. It is not too late for the societies to abandon their propaganda against the officially licensed systems of experiments on animals and to concentrate upon other and more admirable forms of animal welfare. The price of remaining charitable for the purpose of exemption from the law against perpetuities is to be less uncharitable in the simpler meaning of the layman.

BUCHAREST

(FROM OUR OWN CORRESPONDENT)

THE HIGH INFANT MORTALITY

INVESTIGATIONS by Prof. Mezinescu, of the University of Bucharest, revealed a disconcerting rise in the infant mortality in the last decade. In Rumania 50 per cent., that is 12,000 infants, die during the first year, and of the remainder only half reach the fifth year. Not only are our figures higher than any in Europe, says Mezinescu, but what is more sad, the mortality is no lower now than it was fifty years ago. The situation is not much better in the towns than in the villages; the rate is highest in Bessarabia and lowest in the province of Ilfov, containing Bucharest. He drew the attention of the government to the fact that large districts with twenty or twenty-five villages have only one doctor, who is quite unable to treat all the children in the epidemics. There should not be more than ten villages to a district, he said, and there should be a good salary to attract medical men, because the ordinary income from private practice is negligible on account of the great poverty of the rural population.

RECOGNITION OF FOREIGN DIPLOMAS

In the years 1924-34 no less than 1261 foreign diplomates have had official recognition in Rumania. As a rule, said Dr. Peter Stroescu at the annual general meeting of the National Medical Association, such recognition violated the principles of law and of national pride. Some of the diplomas may be acceptable, but most have been obtained with a much shorter period of study than that demanded in the Rumanian universities, and some do not qualify their owners for medical practice even in the country of issue. It is noteworthy, he said, that these diplomas are granted not by the important centres but by small universities which are almost unknown in the scientific world. Another abuse is the permission given to physicians who cannot produce their original documents and licences as evidence of qualification. Having failed in practice after many years in another country, they do not meet any difficulty when they decide to settle in Rumania. These faults, Dr. Stroescu said, need active and urgent remedy, and all the regulations for recognising foreign diplomas must be revised; all who cannot produce original certificates within a certain period should be prohibited from practising. He proposed a rigorous investigation before granting recognition and that a comprehensive examination should be passed. These reforms should also be extended to the registration of dental practitioners. Dr. Tetul, of the University of Bucharest, has said that the foreign diplomas are obtained mainly by Bessarabian Jews and Magyars, and Dr. Danica asked that regulations should be introduced governing the proportion of the different races in medical practice and that the Association should demand that all foreign diplomas should no longer be recognised.

TAXATION OF COSMETICS

A new Act imposes a 10 per cent. ad valorem duty on all cosmetics, even if they contain official drugs. The duty is to be paid in stamps attached to the wrapper in such a way that they are torn in opening the packet. As the list includes hair lotions containing quinine, sulphur, or resorcin; powders containing salicylates and zinc oxide; ointments with ichthyol and mercury; and bath salts with medicinal

properties, a protest meeting was called by the National Medical Association. This will probably result in the withdrawal of these preparations from the list, confining the tax to those that are purely cosmetic.

B C G VACCINATION IN RUMANIA

In spite of all objections, B C G vaccination is considered indispensable by an ever-increasing majority of pædiatricians. This attitude is supported by several articles recently published in this country, among them one by Bradiceanu, who favours intracutaneous injections of the vaccine. The criticisms made are that vaccination is ineffective and that it is harmful. In reply Bradiceanu blames the first on lack of absorption, because so many children vomit the material when it is given by mouth, and he thinks that the intracutaneous method introduced by Wallgren will solve the problem. The principal aim is to attain a relative immunity especially against the primary infection, but the infant has to be guarded for at least two months against every kind of tuberculous contact, and vaccination will not protect him from massive or constant invasions. As to its being harmful, Bradiceanu says that no one has yet proved that the attenuated organism of B C G can regain its virulence; in the absence of reliable statistics, the significance of the slow growth and gastro-intestinal disturbances of vaccinated children cannot be judged.

IRELAND

(FROM OUR OWN CORRESPONDENT)

NATIONAL HEALTH INSURANCE IN THE IRISH FREE STATE

THE committee stage of an amending Bill to the National Health Insurance Acts gave an opportunity in the Dáil last week to draw attention to a peculiar feature of the administration of national health insurance in the Irish Free State. It is that in such administration neither in the central authority of the Controller's office nor in the office of the Unified Society is there a single medical man employed, nor is there any machinery by which medical opinion or medical knowledge is brought to bear on the work of insurance. The Bill before the Dáil was one dealing with the management of the Unified Society which a few years ago replaced the numerous approved societies. An amendment was brought forward to provide that there should be one medical practitioner, to be appointed by the Minister, as a member of the committee of management of the Unified Society. At the end of the discussion the Minister promised to consider the matter and the amendment was withdrawn. When national health insurance was first established in Ireland in 1912 the central authority was a commission of which one of the four members was bound by statute to be a medical practitioner. On the staff of the commission were two medical inspectors. Nearly all the approved societies had medical advisers of their own. Some ten years ago the commission appointed three medical referees to assist them in deciding as to entitlement to sickness or disablement, but these gentlemen have no share in or influence on administration. The commission was abolished some years ago, and as vacancies occurred in the post of medical inspector no fresh appointments were made. The Unified Society, in

PANEL AND CONTRACT PRACTICE

Two Successful Appeals on Specialist Service

AN insurance practitioner has appealed with success against two decisions of the Surrey insurance committee. Both cases related to operations—removal of the appendix and removal of a twisted ovarian cyst—performed at a hospital outside the area of the doctor's insurance practice upon insured patients.

CASE ONE

In the first case an attempt having failed to secure a bed in a local hospital arrangements were made for the patient's admission to another hospital some distance away. The practitioner, before operating, made it clear to the patient that the operation was outside the scope of medical benefit and that there would be a fee of five guineas, and a further guinea for the anaesthetist. The fees were paid and the patient then applied to the H.S.A. for assistance which was not available. The doctor advised the insured person to apply to his society, but the man wrote to the insurance committee and correspondence between the committee, the doctor, and the patient ensued. The doctor was told by the clerk of the committee that he should have submitted form G.P. 45 to the committee within two days of the date on which treatment was given. The clerk's letter was mislaid and the doctor had to ask for a copy, promising his observations upon the receipt of the copy. He added that it had occurred to him that as the hospital was outside the area of his practice the patient would have no right to call on his services there, and the question whether appendicectomy was within the scope of medical benefit or not would be immaterial.

The clerk's reply indicated that the correspondence had been submitted to the medical benefit subcommittee, that he had been instructed to state that it would appear that the submission of the account to the patient constituted a breach of the terms of service, and went on to ask the doctor to send a cheque for six guineas so that a similar amount might be sent to the patient. The doctor objected that the subcommittee had found him guilty of a breach of the terms of service without receiving any statement from him. He reiterated that he had informed the patient that the operation was not within the scope of medical benefit, and that he had filled in form G.P. 45 on his return home from performing the operation, and to the best of his knowledge and belief posted it. In due course the medical service subcommittee heard the case and took the view that the form G.P. 45 had not been posted; they recorded the opinion that the fee paid by the patient was returnable to him. The insurance committee adopted the recommendation that the terms of service had not been complied with, and that the sum of six guineas should be deducted from the practitioner's remuneration and be refunded to the insured person.

The doctor appealed to the Minister, basing his case mainly on the form of the inquiry and, as the persons appointed to hear the appeal were not impressed that aspect need not be particularised. But their report, commenting upon the fact that the

doctor did not raise any question regarding the form of the resolution passed by the committee, expresses the view that the Minister could and should do so. Under Article 34 of the Regulations a committee can recover from a practitioner expenses reasonably and necessarily incurred by an insured person owing to the practitioner's failure or neglect to comply with the terms of service, and can repay to the insured person the sum so recovered. But the liability for the fees had been incurred, not by reason of any default on the doctor's part but by reason of a contract voluntarily entered into by the parties, a contract which did not in any way conflict with the doctor's duties under the terms of service. On legal grounds therefore they recommended that the appeal should be allowed. The view of the referees on the merits of the insurance committee's decision may be given in their own words:

"In the first place it will be noted that the decision was to withhold £6 6s., a sum which comprises the anaesthetist's fee of £1 1s. Now it was not suggested that Dr. A. had previously been remiss in sending forms G.P. 45. In fact the evidence led us to suppose that this was the first occasion on which he had charged for an operation on an insured person. Yet, for overlooking the necessity for submitting form G.P. 45, or possibly for merely forgetting to post the form when filled up, the insurance committee propose not only to deprive the doctor of his fee, but also to make him pay out of his own pocket the anaesthetist's fee.

"To our mind such a penalty is out of proportion to the offence."

CASE TWO

In the second case the patient entered the same hospital during the evening of Dec. 23rd, 1934. The operation began about 11.45 P.M. and lasted about three-quarters of an hour, the doctor returning home about 1 A.M. On the same day, Dec. 24th, the doctor wrote to the committee giving details of the operation and of his special experience, stating that he had informed the patient that the operation was outside the scope of medical benefit, enclosing an anaesthetic claim form, and inquiring whether in the circumstances the claim in respect of the services of an anaesthetist would be allowed. The doctor asked for a supply of anaesthetic claim forms as well as of G.P. 45, and inquired whether he would have to submit form G.P. 45 containing the particulars set out in his letter. Correspondence ensued and the case was submitted to the medical benefit subcommittee, who, under the provisions of Article 32 (2) of the Regulations, referred it to the medical service subcommittee. No fee had been charged. The service subcommittee found that the doctor performed the operation on Dec. 23rd-24th, and that form G.P. 45 was received by the committee on Dec. 31st. They reported that the terms of service are explicit that the notification should be on a form to be provided by the committee, and the subcommittee, taking the view that practitioners know that the time is extremely limited in which they are required to furnish the form to the committee cannot avoid the conclusion that the onus is upon the doctor to have the forms in his possession, ready for use, or to take the quickest possible means of obtaining such forms so as to be able to comply with the terms of service.

The insurance committee resolved, on the recommendation of the subcommittee, that in their opinion the terms of service had not been complied with, and that the doctor was precluded from making a charge to the insured person for the treatment given.

(Continued from previous page)

which the several approved societies were merged two years ago, has had no medical adviser on its staff. At present the national health insurance system operating in the Irish Free State performs no functions directly concerned with either the prevention or the cure of disease. It merely administers a number of cash benefits.

It is hardly to be wondered at that the doctor appealed, contending that the insurance committee had acted unreasonably. The report of the persons appointed to hear the appeal is again given in their own words:

"The doctor suggested that Christmas Day and Bank Holiday should be excluded in the computation of time, and that if the clerk had acted promptly in complying with his request for a supply of forms G.P. 45 the return would have been made in time. He also suggested that he had in fact complied with the terms of service by giving full particulars in his letter of Dec. 24th. He alleged that compliance with the terms of service was rendered difficult by the failure of the committee to afford adequate supplies of the forms, and said that only two forms were sent in response to his request of Dec. 24th. He alleged, further, that the clerk had adopted an unreasonable and unfair attitude towards him, and he illustrated his complaint by reference to a paragraph in a letter dated August 3rd, 1935, addressed by the clerk to the Minister of Health in reference to the doctor's appeal. The paragraph reads as follows:

"The substance of the doctor's contentions arises out of circumstances which require examination. It was not until the doctor was informed that a form was necessary and that he was out of time that he replied using words which clearly meant that he proposed to contend that Dec. 24th and not Dec. 23rd was the date of the operation, and it is submitted that this alteration was made for no other purpose but to enable him: (1) to state that he asked for a form in plenty of time, and (2) to use the fact that there had been a day's delay in answering his first letter for the purpose of throwing upon the office the responsibility for his non-compliance with the terms of service."

"The words used here by the clerk seem to contain the innuendo that Dr. A. did not carry out the operation on Dec. 24th, notwithstanding his assertion that he did so, and that in making the statement he was actuated by improper motives. The clerk used words to the same effect at our inquiry. We pointed out that the medical service subcommittee had found that the operation was performed on Dec. 23rd and 24th, and we asked the clerk whether, before deciding to question Dr. A.'s bona fides in this connexion, he had taken any steps to ascertain from the patient or from the hospital authorities whether the operation was completed before the 24th. He said that he had not done so. We need hardly say that the suggestion contained in the paragraph involves a serious reflection on Dr. A.'s character, and it should never have been made without first taking all possible steps to ascertain the true facts of the case; and we cannot help thinking that the clerk's action in this matter gives some support to Dr. A.'s allegation of unfairness on the clerk's part."

"We are not aware of any authority for the view that Christmas Day and Boxing Day should be excluded in the

computation of time, and we are forced to the conclusion that, on a strict construction of Clause 10 of the terms of service, Dr. A. failed to furnish the insurance committee with form G.P. 45 within the prescribed time, and that, consequently, any demand for payment of his fees would amount to a breach of the terms of service which would render him liable to disciplinary action. Having regard, however, to the fact that the insurance committee was immediately furnished with full particulars of the operation and that Dr. A. forwarded form G.P. 45 to the committee as soon as he could obtain a form from the clerk, we do not think that it was a case in which the committee should have thought it necessary to intervene if a fee were claimed.

"It should be noted that the resolution stated that the terms of service were not complied with. This is tantamount to saying that there had been a breach of the terms of service. As, however, Dr. A. had made no demand for the payment of his fees, it is impossible to hold that there had been any breach, and we accordingly recommend that the appeal be allowed.

"We have not made any direct reference to the clerk's arguments in this case. So far as we can understand them they were to the effect that the provisions of Clause 10 were quite rigid and left no discretion to the committee. We entirely dissent from this view. While it is true that the committee have no power to sanction a breach of the terms of service, we see no foundation for the view that they are bound to examine microscopically every transaction with a view to ascertaining whether there has been some technical departure from the terms of service, however insignificant. We consider that the insurance committee in these above two cases passed resolutions which were ultra vires, adopted an attitude towards Dr. A. which the circumstances did not justify, and put him to unnecessary trouble and expense, and we recommend accordingly that Dr. A. should be awarded costs against the committee."

In allowing the appeals in both cases the Minister directed that the doctor should be awarded five guineas costs against the committee, and practitioners will welcome this indication that the Minister approached the matter from a common-sense point of view. It is a pity that the committee were so insistent on the letter of the law that they appear to have blinded themselves to its spirit. In the second case, in particular, a reasonable person might well ask what details other than those given by the doctor in his letter of Dec. 24th would or could have been included in form G.P. 45—and anyhow who would seriously contend that either an appendicectomy or the removal of an ovarian cyst is other than a specialist service?

PUBLIC HEALTH

The Building Line in London

THE Town and Country Planning Act of 1932 gave the London County Council general control over the development of London, and therewith of the height of any buildings to be erected. The relevant committee in a report to the Council presented on Tuesday does not wish to enforce a general standard height throughout the county; it prefers to be guided partly by the traffic problems of the area but more especially by the need for ensuring sufficient light and ventilation for the buildings erected, particularly on the lower floors. The needs vary according as the area is (1) of a central business nature or chiefly used for basic industry; (2) residential but unsuitable for single family dwelling-houses; (3) suitable rather for family dwelling-houses than for multiple dwellings. In its model clauses the Ministry of Health has already suggested a limita-

tion in the height of buildings based on a maximum overall height restriction with an angular limit, and the L.C.C. town-planning committee has now arrived at a formula applicable to the three building zones indicated. In the third zone in which single family dwelling-house development is likely to predominate the height in feet is to be limited to 40 for dwelling-houses, whether single or multiple, and 60 for industrial buildings, the height not to exceed in any case the width of the street. In the multiple dwelling area the height of the single dwelling-house has the same limitation but the multiple dwelling may be 60 feet high and the industrial 80 feet. In the central zone the limit in each category may be exceeded by another 20 feet; and the height may be $1\frac{1}{2}$ or $1\frac{1}{3}$ times respectively the width of the street. Higher buildings may be permitted in special circumstances or special restrictions imposed in the neighbourhood of ancient monuments. The plan specifying the zones is to be issued before Easter.

Mr. Coste's Retirement

On April 8th Mr. J. H. Coste, F.I.C., chemist to the L.C.C. public health department, will reach the retiring age. Mr. Coste entered the Council's service in 1894, became chief assistant to the late Mr. Frank Clowes, D.Sc., in 1908, and when the chemical work was transferred to the public health department in 1913 he was given the designation of chemist in that department, and appointed official agricultural analyst for the county. The establishment committee

in announcing his retirement remarks that Mr. Coste has for many years held a very high position in the chemical world; his work with its extensive variety of analytical and experimental duties has been of great value to the Council, and by his retirement the Council is losing the services of a distinguished member of its staff. Mr. Coste is an authority on the treatment of sewage, technical gas calorimetry, and the investigation of fog and smoke; he has long been a member of the atmospheric pollution committee constituted by the Department of Scientific and Industrial Research.

THE SERVICES**ROYAL NAVAL MEDICAL SERVICE**

Surg. Cpts. G. V. Hobbs to *Ganges*; T. Creaser to *Pembroke* for R.N.B.; and E. C. Holton, O.B.E., to *Pembroke* for R.N.B., and for duty with S.R.A., R.N. Hospl., Chatham, as Naval Health Officer, Nore Command.

Surg. Comdrs. A. H. Harkins to *Victory* for R.N.B.; W. E. Heath to *Drake* for R.N.B.; and G. E. D. Ellis, O.B.E., to *Drake* for Devonport Dockyard.

Surg. Lt.-Comdr. (D.) R. J. M. Andrews to *Victory* for R.M. Infirmary, Portsmouth.

Surg. Lt.-Comdr. R. R. Baker to rank of Surg. Comdr.

Surg. Lt. W. F. Viret to *Tern*.

Surg. Lt. (D.) S. R. Wallis to *Neptune*.

A. F. Ferguson, J. B. Morris, H. P. L. Rhodes, and D. N. Williamson, as Surg. Lts. (D.) entered for short service, and apptd. to *Victory* for R.N. Hospl., Haslar.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdr. R. B. H. Wyatt placed on Retd. List.

Surg. Lt. W. G. Campbell, M.B., to *Pembroke* for R.N.B.

Surg. Lt. (D.) L. B. Hilton to *Drake* for R.N.B.

ROYAL ARMY MEDICAL CORPS

Short Service Commissions: Lts. (on prob.) confirmed in their rank: J. J. Sullivan, M. Kosloff, A. Gleave, J. L. Gordon, A. M. Pugh, J. H. Taylor, D. N. Keys, G. C. Dansey-Browning, S. J. Meyersohn, M. H. P. Sayers, D. P. Stevenson, S. Brown, P. B. Hanbury, G. A. E. Harman, G. A. Weir, H. N. Perkins, J. D. Cruickshank, P. J. Geoghegan, W. N. J. Clarke, and T. D. M. Martin.

Lt. (on prob.) A. R. O. Denton resigns his commn.

REGULAR ARMY RESERVE OF OFFICERS

The undermentioned having attained the age limit of liability to recall, cease to belong to the Res. of Off.: Lt.-Col. R. E. Humfrey, C.M.G., and Maj. J. L. Wood, O.B.E.

Capt. A. Hemingway, from the Supp. Res. of Off. R.A.M.C., to be Capt.

SUPPLEMENTARY RESERVE OF OFFICERS

R. P. Leake to be Lt.

ARMY DENTAL CORPS

Lt. (on prob.) W. F. Finlayson is confirmed in his rank.

Short Service Commissions: To be Lts. (on prob.): R. Edwards, A. F. Town, H. J. Burns-Jones, W. J. Constantine, P. J. Pigott, and R. G. Kent. The undermentioned Lts. (temp. commissions) to be Lts. (on prob.): J. H. Sherwen, C. W. Upton, B. E. French, W. F. O'Carroll, and R. J. Godfrey.

TERRITORIAL ARMY

Capt. D. A. O. Wilson to be Divl. Adjnt., 53rd (Welsh) Div., vice Maj. G. E. MacAlevey, M.C., vacated.

Lts. to be Cpts.: W. D. F. Lytle, B. C. Jennings, J. Tidd, and H. W. E. Jones.

G. O. Brooks (late Cadet C.S.M., Oakham Sch. Contgt., Jun. Div., O.T.C.) and Scott-Russell Trick to be Lts.

TERRITORIAL ARMY RESERVE OF OFFICERS

Maj. R. B. Green, M.B., F.R.C.S., from Active List, to be Maj., Jan. 27th, 1936. (Substituted for the notification in the *Gazette* of Feb. 18th, 1936.)

ROYAL AIR FORCE

Squadron Leaders L. Freeman to R.A.F., General Hospital, Hinaidi, Iraq, for duty as Medical Officer;

T. R. S. Thompson to R.A.F. Station, Andover, for duty as Medical Officer.

Flight Lt. A. L. St. A. McClosky is promoted to the rank of Squadron Leader.

Flight Lt. F. I. G. Tweedie to School of Army Coöperation, Old Sarum.

Flying Offr. W. J. L. Dean to R.A.F. Station, Biggin Hill.

RESERVE OF AIR FORCE OFFICERS

Special Reserve: Flight Lt. D. S. Buchanan relinquishes his commission on completion of service.

INDIAN MEDICAL SERVICE

Maj. W. E. R. Dimond to be Lt.-Col.

The undermentioned officers retire: Col. Sir C. I. Brierley, Kt., C.I.E., and Col. W. T. McCowen, V.H.S.

Col. Brierley, whose name was in the recent New Year honours, was inspector-general of civil hospitals and jails, North-West Frontier Province.

Indian Medical Department: Maj. (Sen. Asst. Surg.) L. V. O. Eason retires.

COLONIAL MEDICAL SERVICE

Miss J. C. Drury, B.Ch., M.R.C.S., L.R.C.P., has been appointed Bacteriologist-Pathologist, King Edward VII. Hospital, Bermuda.

DEATHS IN THE SERVICES

Colonel SAMUEL JOHN THOMSON, C.I.E., I.M.S. (retd.), who died at Mentone on Feb. 27th in his 83rd year, was the son of Mr. J. B. Thomson of Ramsgate, and was educated at St. John's College, Hurstpierpoint, and St. Mary's Hospital. He qualified M.R.C.S. in 1874, was resident obstetric officer there, and later house surgeon at the Kent and Canterbury General Hospital. In 1877 he entered the Indian Medical Service, was gold medallist and Herbert memorialist at Netley, and was with the field force at the relief of Kandahar in 1880, being awarded the medal. In 1890 he became a member of the Leprosy Commission, and in 1896 was Sanitary Commissioner of the N.W. Province and Oudh. In 1902 he served as director of Burgher camps in the Transvaal, receiving the medal with two clasps. In 1898 he was created C.I.E. for services connected with plague and famine, and C.B.E. (Mil.) in 1919. He retired from the service in 1908, but on the outbreak of war in 1914 was appointed commandant to the 2nd War Hospital at Birmingham with the rank of brevet-colonel.

The death occurred on March 9th in London of Sir JAMES MAGILL, K.C.B., Colonel, late R.A.M.C. Son of the late Rev. William Magill of Cork, he was born in September, 1850, educated at Queen's College, Cork, and at University College, London, and took the degrees of M.D., M.S. Queen's University, Ireland, and M.R.C.S. Eng. in 1871. Entering the Army as staff assistant surgeon in March, 1872, he was appointed in 1876 to the Coldstream Guards becoming surgeon-major in 1885, surgeon lt.-col. in 1896, and ultimately colonel in the Army Medical Services. He served in the Sudan in 1884-85 (severely wounded at Abu Klea) and also in South Africa, 1899-1902. For these services he was mentioned in dispatches, received the medal with two clasps and the bronze star, and was again mentioned in dispatches, receiving two medals with eight clasps, and the C.B. (Mil.) in 1900. He was principal medical officer, Egypt, from 1905 to 1907, when he retired. He was appointed organising secretary of the British Red Cross Society in 1910 and the K.C.B. (Mil.) was awarded him in 1917.

CORRESPONDENCE

TREATMENT OF VAGINAL DISCHARGE

To the Editor of THE LANCET

SIR,—It appears that opinions differ considerably upon the subject of *Trichomonas vaginalis*. If one were to believe the literature issued by certain manufacturing chemists trichomonas is common. Mr. Luker says it is very rare. My own feeling is that in gynæcological practice the trichomonas though not common ought to be remembered, for once discovered it is fairly easy to eradicate. The type of case in which trichomonas infection should be suspected is where a discharge persists after routine treatment for urethral and cervical infection, gonococcal or non-specific. In such a case *Trichomonas vaginalis* would appear to be in the nature of a secondary invader, producing its effect when the original infection has abated. The following case is an example:—

A. B., aged 48 years, attended first complaining of vaginal discharge of ten weeks' duration which she had treated herself by douching. Gonococci were found in a urethral smear, and there was slight endocervicitis clinically. She was treated with douches, contramine pessaries, and later with a gonococcal vaccine. After six months' treatment there was clinically neither urethritis nor cervicitis, no pus cells in a urethral smear and few in a cervical smear. There persisted, however, a fairly profuse thick white vaginal discharge in which *Trichomonas vaginalis* was found. After one week's treatment with Devegan the discharge was considerably less, and trichomonas was not found. Treatment was repeated for a further week when discharge had ceased and no pus cells were seen in cervical or vaginal smears.

A vaginitis produced by trichomonas alone is manifested by a frothy yellow discharge and a vaginal wall marked with red spots. This clinical picture is not always seen in its entirety. In an article entitled Non-operative Gynæcological Treatment (Post-Grad. Med. Jour., March, 1936) Dr. V. B. Green-Armytage states that trichomonas infection is responsible for at least 30 per cent. of cases of the infective type of leucorrhœa in virgins. In a series of 25 cases, examined by permission of Miss G. M. Sandes, F.R.C.S., at the out-patient department of the London Lock Hospital (which is attended by gynæcological and urological as well as venereal disease cases), 5 (or 20 per cent.) were found to have trichomonas in the vaginal discharge. These cases conformed mainly to the type described above, and were chosen for investigation for that reason. They are not strictly comparable to the type to which Dr. Green-Armytage refers, but if the two are taken together they illustrate that trichomonas is not a factor to be overlooked in the investigation of any case of leucorrhœa.

The treatment adopted here is as follows: The patient is instructed how to insert a Devegan or Stovarsol tablet into the vagina, and does this each night. In some cases morning douching is ordered. Patients are seen each week and a vaginal specimen examined. In no case has trichomonas been found after one week's treatment, which is then continued until discharge ceases. A further week's treatment is given after the first menstrual period to avoid recurrence during the alkaline tide.

It would appear that Devegan, Stovarsol, Spirocid, and Orarsan are of equal service in this condition.

I am, Sir, yours faithfully,

JAMES MARSHALL,

March 6th.

Resident Medical Officer, London Lock Hospital.

GASTRIC ACIDITY AND ITS SIGNIFICANCE

To the Editor of THE LANCET

SIR,—Dr. A. F. Hurst's comments in your issue of Jan. 18th are of great interest to me because with a large mass of evidence and his great experience he has been able to confirm results which we hope to publish in the near future. Thus it has also been the experience of both Alvarez and ourselves (private communication) that the acidity remains high in gastric and duodenal ulcer in spite of severe hæmorrhage, and in certain other cases with gastric symptoms. We have also found free acidity in severe anæmias of other types. In my paper of Jan. 4th, however, I was not concerned with these cases, but confined myself to the hæmorrhagic anæmias without gastric symptoms. Further experience certainly seems to show that I have probably erred in placing my achlorhydria-hæmoglobin level too high. Whatever this level may be it is, after all, only an average, with, as I stated, considerable individual scattering above and below.

That the achlorhydria in our cases is secondary to the hæmorrhagic anæmia is shown by the fact that free acid appears and later rises with improvement in the blood condition. (Some individuals of course have achlorhydria throughout.) Further, in animals we can produce lowering of the acid at will by bleeding, and this condition remains as long as the animal is anæmic. The full details of these observations will be published in the near future.

As regards the effect of asthma, I was quite well aware that gastric acidity is commonly low or absent between attacks. But I threw out a suggestion that it might be of interest to investigate the effect of asthma on gastric acidity during the attack. Does the rise of plasma CO₂ during an attack raise acidity? Or does the accompanying anoxæmia have the opposite effect? I can find no information on the question.

I am, Sir, yours faithfully,

FRANK L. APPERLY.

Medical College of Virginia, Richmond, Virginia, U.S.A.,
Feb. 26th.

OPERATION FOR FEMORAL HERNIA BY A
MIDLINE EXTRAPERITONEAL APPROACH

To the Editor of THE LANCET

SIR,—In reference to Prof. A. K. Henry's article in THE LANCET last week (p. 531) may I refer him to the *Proceedings of the Royal Society of Medicine* (vol. xv., No. 4, 1922, p.13). He will see there that I described a midline extraperitoneal approach for inguinal and femoral hernia. The only modification I would make to that description is that I see no reason for not operating on younger patients. I would point also to the care that is necessary to avoid injury to the ureter in operating on femoral hernia.

I am, Sir, yours faithfully,

March 9th.

G. LENTHAL CHEATLE.

PROGNOSIS IN SPINAL CARIES

To the Editor of THE LANCET

SIR,—It is rather irritating to find an otherwise carefully compiled article seriously marred by figuring which will not stand careful scrutiny. In to-day's issue of THE LANCET there is an unfortunate example of this in the article Prognosis in Spinal Caries on page 562. Apparently the total number of cases

under review was 1666; of these 1582 cases were discharged during the period and 61 died. No mention of the 23 cases required to make up the total. Percentages are usually shown in relation to the total number treated, and in this case in my opinion they should be represented in this way:

Total number of cases	..	1666 = 100 %	
Discharged	..	1582 =	95.00 %
Died	..	61 =	3.64 %
Unaccounted..	..	23 =	1.36 %
			100.00 %

In "Causes of Death" the figures given in the first instance are—

Miliary T.B and meningitis	32
Sepsis and amyloid disease	16
Other causes	13

but if the tabulated figures are added up we get 32, 15, and 14 respectively. In an investigation of this kind it would probably be better to deal with only those cases in which a conclusion has been reached, and in this way the figures should be shown thus:

Total cases the outcome of which is known	1643
Discharged	1582 = 96.3 %
Died	61 = 3.7 %

As figures given in THE LANCET are frequently quoted in support of various theories it is very desirable that they should be clear and not capable of misinterpretation. I can offer no criticism of clinical observations but I can check the deductions when figures are involved and shall continue to dispute any theory put forward in the popular press which is founded on a fallacy. In the present case the discrepancy is not great but the fact that the death-rate is over-stated reduces the credit due to Sir Henry Gauvain for the excellence of his treatment which gives a death-rate only a little over three times that of the whole population.

I am, Sir, yours faithfully,
S. D. PERSY FISHER.

The Crescent, Alwoodley Park, Moortown, Leeds,
March 7th.

AN ADDRESS IN HARLEY STREET

To the Editor of THE LANCET

SIR,—I wonder whether any of your readers have noticed that within the last year or so the names appearing on door-plates in the Harley Street district have begun to introduce a continental note, so that the kudos of an address in this area is now international rather than national. When the doors of our hospitals and medical schools were thrown open a short while ago to medical refugees from another country it was expressly stated to those of us who are teachers at the medical schools that the Home Office were granting permits for these refugees to reside in this country for the purpose of obtaining a British qualification, but that they would not be allowed to practise here.

On this understanding we undertook, wrongly as I think, to teach these graduates of a foreign university with our undergraduates in the same classes and clinics. What has been the result? The harvest of British diplomas has been gathered, but there are no signs of our guests departing from our shores to practise elsewhere. On the contrary, hardly a week passes without my receiving an application from one of the new recruits to British medicine to be one of my clinical assistants; there is hardly an election for a minor staff appointment without the appearance as candidates of one or more; and, as I stated in the beginning, the crop of plates bearing continental

names increases daily. The reason given by one applicant for a clinical assistant post was, not that he wished to learn more of a particular subject, but that he thought it would help him to improve his knowledge of English. Another applying for the post of registrar, when asked whether it was his intention to practise his specialty in England, said, with the greatest assurance, "Oh! Yes" without any idea that it was a rare privilege for him to do so. Only yesterday I received a card in an open envelope from one of these gentlemen in which he acquainted me of the fact that he was a gynæcologist and surgeon, and that he had now established himself in the consulting area.

Surely this is a matter for investigation by those bodies representing medical interests in this country. It is already difficult enough for our younger men to make a living. The fact that I am on the staff of one of our teaching hospitals makes it necessary for me to claim the privilege of anonymity, but I enclose my card.

I am, Sir, yours faithfully,
London, March 7th. ALBERICUS.

STAMMERING

To the Editor of THE LANCET

SIR,—Mr. St. John Rumsey suggests that I seem to contradict myself but does not indicate in what way. In case, however, I did not make myself sufficiently clear in my letter of Feb. 22nd permit me to restate the matter. It is now definitely established that stammering is a psychic trouble which deranges the natural coördination of the muscles of respiration, voice, and articulation, bringing about faulty action of all of these. Consequently neither psychic treatment alone nor elocutionary instruction alone—nor indeed elocutionary treatment at all—can effect cure. Psychic analysis to remove fear and relaxation treatment to remove the muscular contractions caused by the fear are essential. These must be followed by re-education and coördination of all the muscles concerned in speech. To employ elocutionary measures is to focus the stammerer's attention on the symptoms, making matters infinitely worse. The most difficult cases to treat have in my experience been those where elocutionary instruction has been tried.

The dictionary tells us that elocution is "The art of effective speaking, more especially of public speaking, regarding solely the utterance or delivery; *eloquence*" (the italics are mine). Obviously therefore elocution does not in any way touch the cause of stammering.—I am, Sir, yours faithfully,

KATE EML-BEHNKE.
Earl's Court-square, S.W., March 9th.

REGULATION OF PROSTITUTION

To the Editor of THE LANCET

SIR,—Some of your correspondents have expressed doubt at my statement (in your issue of Nov. 9th, 1935, p. 1078) that the Congress of Dermatology meeting at Budapest last autumn "accepted as a fact that syphilis and gonorrhœa could be made extinct throughout the world within a single year if all who suffer from them would have themselves fully treated." It is true that no such direct statement was made from the rostrum, but from the discussion held on Sept. 13th, in No. 4 hall of the Hungarian Scientific Academy, on the international campaign against venereal diseases the inference could be drawn that, with adequately thorough treatment, gonorrhœa as well as syphilis, at whatever stage of the disease, could be brought within

a year or so to such a phase as not to be infectious any more. Hereditary syphilis, as stated by Hoffmann (Bonn) and Guszmann (Budapest), will shortly disappear from all civilised States. I quote their statements *literatim*.

Prof. J. GUSZMANN (Budapest): In the domain of syphilidology I see the greatest progress in the fact that to-day we are justified in asserting that congenital syphilis will shortly disappear entirely in all cultured countries and their terrible consequences will remain unknown to the next generation of physicians.

Dr. E. HOFFMANN (Bonn): As I have already emphasised in articles which have appeared in the *Wien. klin. Woch.* and the *Wien. med. Woch.*, with the aid of our present methods of intensive treatment congenital syphilis is well avertable and certainly curable. In consequence of this fact stillborn and macerated fetuses have entirely disappeared at many places (Germany, Denmark) where intensive and persistent treatment is applied.

From these premisses we can infer, without undue optimism, that sexual diseases could be made extinct within a year or so, if during this time we could enforce the strict and complete isolation of the patients, whereby the source of infection could be blocked. It is equally reasonable to imagine that by the enforcement of severe procedures—eventually punishment and internment—adopted internationally against venereal patients caught or reported to spread the diseases at large and by applying treatment on them the infectivity of such patients would cease and as a consequence venereal disease would disappear. Laws to this effect are already in force in Germany and Rumania; a draft Act has just been prepared in Hungary.

I am, Sir, yours faithfully,

YOUR BUDAPEST CORRESPONDENT.

Budapest, Feb. 27th.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Home Office Administration

On March 5th, on a vote for the Civil and Revenue Departments, Mr. BENSON raised the subject of the

PSYCHOLOGICAL TREATMENT OF DELINQUENTS

He acknowledged with gratitude the sympathetic way in which the Home Office had dealt with this matter in the past. The first official recognition of the psychological problem or the possibility of the psychological treatment of delinquents and criminal offenders was in a Departmental Report issued in 1932. The Home Office immediately appointed a psychiatrist who he believed was working at Wormwood Scrubs. His object in raising the matter that day was to appeal to the Home Office to go a little bit further.

It was true, he said, that the psychological treatment of delinquents was in a purely experimental stage, but so was the treatment of cancer. In practically all medical matters treatment and experiment were bound to go hand in hand. With regard to psychiatry particularly as applied to delinquency it was essential that psychiatrists should be encouraged in their work on the subject and allowed every possible facility for the treatment of delinquents in order that they might extend and improve their technique and bring it out of the experimental stage. At present the work was extremely haphazard very largely owing to the shortage of facilities. It was not that the Home Office was responsible for that. There was a brilliant band of psychological specialists working on this matter but unfortunately they had to apply a long, arduous, and extremely difficult technique, and they were gravely hampered by lack of funds, lack of buildings, and lack of almost everything that would make either their experiments or their treatment efficient and helpful. At the present moment there was a single Government psychiatrist he thought at Wormwood Scrubs, and there were six London hospitals which had psychological clinics, and these occasionally took delinquents. There was the Institute of Medical Psychology, where again the treatment of delinquency was a side line, though they had done most valuable work and had gathered very valuable data. There was also one small new body—the Institute for the Scientific Treatment of Delinquency—which was the only specialist body in the country dealing with the psychiatric treatment of crime and criminals.

The type of case that came before these clinics for treatment was extraordinarily varied. It was not merely the sex case as so many people seemed to imagine. In 1934 and 1935 the following cases came

into the hands of the Institute for the Scientific Treatment of Delinquency:—

Attempted murder ..	1	Theft (including four burglars) ..	46
Violence ..	7	Shop lifting ..	14
Attempted suicide ..	9	Embezzlement, forgery, and false pretences ..	26
Sex cases ..	36	Other kinds of cases ..	29
Wandering ..	13		

In dealing with this subject, Mr. BENSON continued, the Home Office would have to get the coöperation of judges and magistrates. In London he was glad to say the magistrates were awakening to the importance of the matter. In 1935 they sent to the Institute for the Scientific Treatment of Delinquency twice as many cases as they sent in 1934. In the second place the Home Office would have to realise the necessity for the provision of treatment for cases in which it was recommended by the courts. In London the possibilities for this treatment were hopelessly inadequate and in the provinces they were entirely non-existent. It was a really staggering fact that outside London there were only four doctors with the qualification of the Institute of Psycho-Analysis. All the rest of the doctors with that qualification were in London. There was one doctor in Manchester, one in Reading, one in Southsea, and one in Edinburgh. The Home Office would have to face this problem because the psychiatric treatment, not merely of delinquents but of any neurotic person, was fundamentally different from that given by the hospitals. To allow this type of treatment to depend on the voluntary work of a small handful of specialists was out of the question. If this problem was to be thoroughly tackled the Home Office sooner or later would have to provide its own trained psychiatrists and to regard this as a curative branch of the prison service.

SILICOSIS—MINERS' NYSTAGMUS

Mr. HOLLINS drew attention to the position of hundreds of thousands of workers engaged in occupations in which the dreadful disease of silicosis had developed. He would prefer that there should not be the present limitation with regard to silicosis because Section 47 of the 1925 Act only scheduled the occupation and not the disease. Wherever a workman contracted this dreadful disease as a result of following an occupation he should be allowed to make a claim for compensation. Under the scheme of Section 47 of the 1925 Act, and the amending Act of 1931, medical boards were introduced and the experience of the pottery industry was that these boards were operating in a perfectly satisfactory manner. The workers would prefer the medical boards to the system of medical referees and certifying surgeons. They preferred that there should be a second or third opinion rather than that the decision should be

left to one man. They could see no reason why silicosis should not be scheduled as a disease so that medical boards would administer the matter.

Mr. TINKER raised the question of miners' nystagmus and urged that the Home Office should consider having more than one medical man to judge these cases. He thought there should be at least three. The medical referee might be right in his judgment but the workman always felt that he had not had a fair deal.

ACCIDENTS IN FACTORIES AND WORKSHOPS

Mr. SHORT called attention to accidents in factories and workshops. He said that judging from the last report of the Chief Inspector of Factories there had been a notable increase in the number of accidents, particularly of a non-fatal character, and the inspector emphasised the growing volume and nature of the accidents. There was need for greater care and supervision. The accident rate among young people was much greater than the rate among adults. The inspector's report also drew attention to the need for greater care and supervision in order to deal with accidents in connexion with hoists and lifts. He thought that they had not enough inspectors and he hoped that the Government would agree to appoint a larger number. He also called attention to carbon monoxide poisoning arising from petrol fumes. Many drivers and other workers employed on petrol-driven omnibuses suffered from gastric complaints from inhaling these fumes. There ought to be a closer association with the medical profession as regards the health of the workers. There should be a greater diffusion of knowledge concerning industrial diseases. Medical men ought to be encouraged if they believed that a complaint from which a patient was suffering arose from the patient's occupation to communicate that fact to the Home Office.

THE UNDER-SECRETARY'S REPLY

Mr. GEOFFREY LLOYD said that with regard to the psychological treatment of delinquents the Home Office, while keeping its mind thoroughly open to all new schools of thought, would not rashly adopt schemes or theories which were not yet thoroughly tried out or approved. Psychologists had not achieved complete agreement among themselves. The Home Office had sent a circular to courts of summary jurisdiction in which they drew attention to the desirability of obtaining a medical report on the offender in any case where the circumstances of the offender or his demeanour when before the court suggested doubt as to his mental condition. That was only one side of the question. It might well be that there were some offenders who were not mentally normal and who ought to be under some form of restraint but who could not be dealt with except by being sent to prison. The Home Office had appointed a specialist in mental psychology as part-time medical officer at one of the London prisons. It was too early to arrive at any conclusions as to the type of case which was most likely to respond to such treatment or to give permanent results.

The Home Office would, he said, look into the points raised about industrial disease and accidents. There was a committee sitting on the subject of miners' nystagmus. With regard to silicosis, it was very slow in its onset and that was one reason why it was not suitable to be scheduled under the ordinary provisions. The other reason was that it was difficult to diagnose. In general the Home Office felt that it was not wise to scrap all the work that had been done in gradually building up this complex system of silicosis schemes which had been added to and improved as the result of experience. It was better to go on experimenting on and making researches into the causes of the disease and they were ready to examine any evidence as to the occurrence of the disease in any other occupations or circumstances, and so in time to make improvements. At the present time the Home Office were conducting a number of examinations on silicosis and in particular

the Medical Research Council was at work on the subject. The prevention of silicosis was also receiving attention. The Department was alive to its function of assisting in the prevention of accidents. He drew attention to the Industrial Museum in Horseferry-road. The Department had a clearing house for knowledge from all parts of the country in relation to safety, health, and welfare in factories. The question of carbon monoxide poisoning among drivers of petrol-driven vehicles was being examined by a medical committee at the present time.

Alcohol and Road Accidents

In the House of Commons on March 4th, Mr. C. C. TAYLOR, moving a resolution urging H.M. Government to press forward all possible measures to achieve reduction in road accidents, remarked that the drunken motorist should be treated as a criminal lunatic; but he submitted that a moderate amount of alcohol had no more effect in producing accident than had severe shock or excitement, and if a man was moderate in his ways it would not affect him when he drove a motor-car.—Dr. SALTER, who followed, insisted that a far greater danger than actual drunkenness was the "subintoxicated" motorist. The British Medical Association, he said, improvised this term to indicate a person who though not obviously under the influence of drink in the legal sense was none the less physiologically under the influence of drink. Notwithstanding the expert advice given to him the Minister of Transport, he said, had taken no steps to bring the extreme danger of consuming alcohol, before driving or when driving, before the motoring public, and this in spite of specific evidence brought to his notice that the consumption of even quite small quantities of alcohol led to a reduction in the efficiency and capacity of the driver. The Minister having asked for the advice of the B.M.A. had not only failed to give publicity to the conclusions of its committee but had poured ridicule on them. Other nations, said Dr. Salter, had brought the danger of small quantities of alcohol before every driver and every applicant for a license or its renewal. In Germany every applicant was handed a card on which he was warned not to touch alcohol even in small quantities before he started to drive; he had to sign a book in the police president's office declaring he had received the card and had read and understood it. In the judgment of many experts, said Dr. Salter, at least 25 per cent. of the fatalities and accidents on the roads were due to the fact that drivers were subintoxicated.—Sir ERNEST GRAHAM-LITTLE, who asked the Minister for a more thorough investigation of the causes of accidents on the road, said it had been shown that about one-quarter of the population at any given time were definitely prone to accident, and this accident-proneness could be identified by suitable tests. It should be possible, he thought, to introduce if only on an experimental basis such tests for a portion of the persons concerned.—Mr. HORE-BELISHA, in replying, remarked parenthetically that the development of roads like the growth of forests was a long process. He denied suppression of the B.M.A. report, remarking that it was published at sixpence a copy, while Dr. Salter wanted it to be published at the Government's expense. Doctors having undertaken this work he did not see, he said, why the medical profession should not get what advantage they could from the sale of the report. Anyone who desired to do so could read the report and learn that there was no proposal emerging from it which the Minister could put into operation. Mr. Hore-Belisha added that he mentioned the subject in the Highway Code for the first time.

Sir FRANCIS FREMANTLE intervening suggested that what the Minister had said did not in the least enforce the particular point of the medical inquiry which was to bring it home to people that the least quantity of alcohol before driving a car involved danger.—The MINISTER rejoined, "I agree with my hon. friend that the B.M.A. laid it down

that alcohol even in small doses was liable to have a bad effect on the driving of a car, but it does not fall to me to operate their recommendation. I cannot prevent people who have taken some alcohol from driving cars; I can only call attention in general terms to the matter. I have indicated in the Highway Code that it is undesirable that motorists should drink when they are going to drive cars, and I do not think that I can do more than that."

The Minister indicated that in coöperation with the Home Secretary and the Secretary for Scotland he was this year as from April 1st making an analysis of all accidents involving death or injury.

Milk Supplies and the Problem of Nutrition

In the House of Lords on March 10th Earl DE LA WARR Parliamentary Secretary to the Board of Education, moved the second reading of the Bill which extends for a further 18 months the provisions of the Milk Act, 1934.

Viscount ASTOR said that as chairman of the League of Nations Commission he knew what was being done under the auspices of the League to develop a nutrition policy in this and other countries. The movement in that direction was very largely due to the work of Earl De La Warr. The fact was beginning to be appreciated that if children had an ample supply of milk they would become healthier and better citizens. It was unlikely that there would be a spectacularly large increase in the consumption of milk through the supply of cheap milk to schools, but he hoped that the increase would be steady. Unless the price of milk to the consumer could be substantially lowered there would not be the full consumption of milk which was desired. Three ways by which the price of milk could be lowered were, reduction in the price of distribution, reduction in the cost of production, and a subsidy. Something should be done along these three lines. There was a very large surplus supply of milk because the producers' price was too high; the aim should be to produce as much cheap milk as possible.

The Bill was read a second time.

HOUSE OF COMMONS

WEDNESDAY, MARCH 4TH

Maternal Mortality in Glasgow and Greenock

Mr. DAVIDSON asked the Secretary of State for Scotland the figures of maternal mortality for 1935 in Glasgow and Greenock respectively.—Sir GODFREY COLLINS replied: The number of maternal deaths in Glasgow in 1935 was 155 and in Greenock 11, representing rates of 7.0 and 6.5 per thousand births respectively.

Medical Examination of Air Pilots in Scotland

The Marquess of CLYDESDALE asked the Under-Secretary of State for Air whether, in view of the large increase of commercial pilots in Scotland and the expense and inconvenience to which they were placed in presenting themselves for medical examination in London, he was prepared to authorise the appointment of a Medical Board for Scotland, either in Glasgow or Edinburgh, to include an approved resident doctor, which board would refer borderline cases to the central board in London.—Sir P. SASSOON replied: I regret that the number of applicants from Scottish addresses does not justify the setting up of a special board in Scotland. Medical examination in London is ordinarily only insisted upon in connexion with the initial grant of the licences, when the candidate's presence in London is in any case necessary, for the technical or flying test, and once in every two years subsequently.

Sounding of Motor Horns and Fatal Road Accidents

Mr. BOULTON asked the Minister of Transport if he was aware that coroners in several cases had made severe strictures on accused persons for not sounding their motor horns after hours, causing fatal accidents; and if he was still satisfied that this law was serving a useful pur-

pose.—Mr. HORE-BELISHA replied: I am aware of one such case. I am amply satisfied that the law is serving a useful purpose, and I should imagine that coroners generally, like other citizens, assist in its observance.

THURSDAY, MARCH 5TH

Occupational Diseases Convention

Mr. CREECH JONES asked the Home Secretary whether the Government had given recent consideration to the ratification of the Workmen's Compensation (Occupational Diseases) Convention (Revised), 1934, No. 62; and when it was proposed that the Convention should be ratified.—Sir JOHN SIMON replied: The Government propose to ratify this convention and the formalities for ratification are now being carried out.

Accidents Convention 1925 (No. 17)

Mr. CREECH JONES asked the Home Secretary whether he would now consider, with a view to ratification, the Workmen's Compensation (Accidents) Convention, 1925 (No. 17).—Sir JOHN SIMON replied: I am advised that this convention could not be ratified without far-reaching changes in the law and medical arrangements of this country, and I see no prospect of such legislation being passed at present.

Gas Mask for Civilian Protection

Mr. SHORT asked the Home Secretary whether he would arrange for Members of this House to attend a demonstration of the gas mask to be used for the protection of the civilian population.—Mr. G. LLOYD replied: When the design of the respirator referred to is finally settled, I shall be very glad to arrange for a demonstration, and I hope that hon. Members will not merely attend but also test for themselves the efficacy of the respirator in various concentrations of poison gases.

Protection of Public against High Explosive and Incendiary Bombs

Lieut.-Commander FLETCHER asked the Home Secretary what precautionary instructions, in addition to those against gas attacks, he was sending to local authorities with regard to attacks by high explosive and incendiary bombs.—Mr. G. LLOYD replied: It is hoped to issue handbooks and memoranda making available to local authorities, industrial undertakings, and the public generally the information at the disposal of the Government on protection against high explosive and incendiary bombs; and I can assure the hon. Member that this aspect of the subject is being given the careful consideration which it requires as an integral part of all air raids precautions schemes.

Law and Practice Relating to Coroners

Viscountess ASTOR asked the Home Secretary whether it was proposed to introduce a Coroners Amendment Bill, following the recent publication of the report of the departmental committee which inquired into the law and practice regarding coroners.—Sir JOHN SIMON replied: Legislation would be required to give effect to a number of the committee's recommendations, but I cannot make any statement until there has been an opportunity of giving full consideration to the report.

Boy Patient at Napsbury Mental Hospital

Mr. MESSER asked the Minister of Health if he was aware that John Henry Fuller, a boy of 14 years of age, was the only boy patient in the Napsbury mental hospital, where all the other patients are adults; and if he would take steps to obtain his transfer to a more suitable institution.—Sir KINGSLEY WOOD replied: The question of this patient's transfer to another institution has already been carefully considered, but I am advised that it is not at present desirable or practicable, having regard to his mental condition, as to which I am communicating with the hon. Member.

Maternity and Child Welfare in Wales

Mr. WILFRID ROBERTS asked the Minister of Health whether his attention had been called to figures and

graphs showing the reduction of maternal mortality in the Rhondda valley as the result of the provision of additional meals as well as milk to expectant mothers; and whether he would supply these figures and graphs for the information of Members.—Sir KINGSLEY WOOD replied: I have requested the medical officers of my department who are investigating the problem of maternal mortality to pay careful attention to the information regarding Rhondda referred to by the hon. Member. I have no doubt that they will deal with it in their report which I hope to receive from them when they have completed the extensive inquiry they are now making. The report, which will be presented to Parliament as soon as it is received, will, I think, be the best way of bringing to the notice of hon. Members the facts in this and other cases, and the conclusions to be drawn from them.

MONDAY, MARCH 9TH

Health Conditions in a Factory

Mr. CREECH JONES asked the Home Secretary whether his attention had been drawn to the conditions of work at the Cotopa mills, Guiseley; whether he was aware of the bad physical effects of such employment; whether he would ask the inspector of factories to give special attention to the processes carried on in this mill and consider scheduling the work under the list of dangerous trades; and in the meantime if he would impose rigid rules to govern the period of actual work on the respective processes, insist on mechanical draught by fan being employed to remove fumes and gases and the provision of adequate washing facilities, and the taking of meals by the workpeople in places other than in the mills.—Mr. GEOFFREY LLOYD replied: It appears from a report by one of the medical inspectors of factories who has visited these mills that no serious trouble has arisen, but that some of the employees have suffered from sore eyes due to fumes. It would seem that this can be prevented by improved ventilation in the process room, together with more care on the part of some of the men to wear the goggles provided for them, and methods of improving the ventilation are to be discussed with an inspector. A canteen with messroom and washing accommodation is being built. There appears to be no case on grounds of health for restricting the hours of work or for prohibiting the taking of meals on the premises, but the works will continue to receive special attention.

Bombing of British Red Cross in Abyssinia

Mr. COCKS asked the Secretary of State for Foreign Affairs whether he could give the House any information regarding the bombing of the British Red Cross hospital at Karen; and whether H.M. Government had made a protest to the Italian government against this breach of international law?

Sir ASSHETON POWNALL asked the Secretary of State for Foreign Affairs whether he had any information with regard to the bombing by the Italians of a British Red Cross ambulance.—Viscount CRANBORNE, Under-Secretary for Foreign Affairs, replied: On March 5th H.M. Minister at Addis Ababa telegraphed a message from Dr. Melly, the leader of the British Red Cross ambulance in Northern Ethiopia, stating that the British ambulance was heavily and deliberately bombed at midday on March 4th while situated in the open on Korem plain, two miles from the nearest troops. There was a Red Cross ground flag 40 feet square in the centre of the camp, and red crosses on the tents and the flagstaff. The operation, sterilisation, and three ward tents were destroyed, as well as one lorry. Three patients were killed and several wounded. There were no casualties amongst the personnel. The aeroplane, according to the message, circled low over the camp nine times, dropping about forty bombs, one of which fell on the ground flag. The message added that the camp had previously been observed many times at Waldia, Allamata and Morem by low-flying aeroplanes. It has subsequently been reported that the ambulance was again bombed on March 5th. On the receipt of the first telegram from H.M. Minister at Addis Ababa, H.M. Ambassador at Rome was instructed to lodge an immediate protest with the Italian Govern-

ment on the facts as stated by Dr. Melly, and to make it plain that H.M. Government expect them to order an immediate investigation and, in the meantime, to issue the strictest instructions against a recurrence of this incident. In reply to this communication, Signor Suvich, while not prepared to admit the accuracy of Dr. Melly's report, nevertheless stated that an inquiry would be instituted, and that instructions would be issued to avoid a repetition of the incident. On receipt of the news that the second bombing incident had taken place, my right hon. friend instructed Sir E. Drummond to renew his representations in the strongest manner and to ask for an assurance that the necessary instructions had been issued and their receipt acknowledged by the Italian military authorities. The result of these further representations is not yet known.

Sir A. POWNALL: Has the noble lord any information with regard to the death of Major Burgoyne and has his attention been called to a statement in the *Times* on Saturday by their Special Correspondent who himself saw this episode, that the bombing was unquestionably deliberate?

Viscount CRANBORNE: That is a different question.

TUESDAY, MARCH 10TH

Erysipelas Deaths

Mr. VIANT asked the Minister of Health whether his medical staff had formed any opinion as to the cause of the marked increase in the number of deaths certified as being due to erysipelas during the years 1930 to 1934.—Mr. SHAKESPEARE (Parliamentary Secretary to the Ministry of Health) replied: The incidence of this disease, the increase of which is only one manifestation of the increased prevalence of a group of diseases of similar causation which has tended to occur in waves of a few years' duration, is receiving the attention of my right hon. friend's medical advisers, but he is advised that no firm conclusions are at present possible as to the reasons for this periodicity.

Voluntary Patients in Public Mental Hospitals

Mr. SORENSEN asked the Minister of Health the number of voluntary patients in public mental hospitals during the last week of 1935.—Mr. SHAKESPEARE replied: The figures are not available for the last week of 1935, but on Jan. 1st last there were 4296 voluntary patients in public mental hospitals, and 229 in the Maudsley Hospital.

Medical Opinion and Fitness for Light Work

Mr. HARDIE asked the Secretary of State for Scotland whether, in view of the number of cases coming under the Scottish Health Department, where men were being told by medical opinion that they were only fit for light work, he could give a definition of what constituted light work; and on what grounds his department said that a man was fit for work when certified as suffering from mitral stenosis.—Sir GODFREY COLLINS replied: The cases which the hon. Member has in mind are presumably those of persons who have been examined by the regional medical officers of the Department of Health on the question of their incapacity for work. If and when the opinion is expressed that the persons concerned are only fit for light work the phrase "light work" is used in its ordinary sense, that is, as indicating work not involving physical effort of an arduous nature. With regard to the last part of the question, I am advised that mitral stenosis does not necessarily involve incapacity for all kinds of work.

AN ANONYMOUS DONOR.—On March 6th Mr. Henry Ward, formerly well known as a civil engineer, died at the London Hospital at the age of 87. In 1923, under a condition of strict anonymity he had given to the hospital £100,000, of which £80,000 was devoted to the general endowment and the remainder to general purposes. Mr. Ward was for 33 years a member of the London County Council and for 30 years he served on the Metropolitan Water Board.

OBITUARY

**JOHN WHEELER DOWDEN, M.B., LL.D.,
F.R.C.S. Edin.**

LATE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF
EDINBURGH

THE death occurred on March 8th of Mr. John Wheeler Dowden, the well-known Edinburgh surgeon, after a brief illness. Born in 1866, the son of the Right Reverend John Dowden, bishop of Edinburgh, he was educated at Merchiston Castle School and the University of Edinburgh. He graduated as M.B., C.M. in 1890 and served as resident surgeon and resident physician at the Royal Infirmary from 1890-92, and in the latter year was appointed resident

MR. DOWDEN

[Photograph by Swan Watson]

physician at the Edinburgh Royal Hospital for Sick Children. He took the diploma of F.R.C.S. Edin. in 1894 and was appointed assistant surgeon to the Hospital for Sick Children, tutor in clinical surgery at the University Medical School, and surgeon to the New Town Dispensary. In 1912 he was appointed surgeon to the Infirmary and lecturer on clinical surgery in the school of medicine of the Edinburgh Royal College of Surgeons, while he was appointed surgeon to the Chalmers Hospital. He served the Royal College of Surgeons of Edinburgh and the University of Edinburgh as an examiner in surgery, pathology, and operative surgery, and examined also in surgery at the University of Durham, while over a long period of years he made valuable clinical contributions to medical journalism, principally to the *Edinburgh Medical Journal*, the *Scottish Medical Journal*, and the *Transactions* of the Medico-Chirurgical Society of Edinburgh.

Alike as surgeon and teacher Dowden was conspicuously successful. He had a fine apprenticeship under Annandale, Cotterill, and Joseph Bell, and he maintained the high standard of the Edinburgh school of surgery on both academic and practical lines. His classes were fully attended and the students learned from him much that he knew would be useful to them in meeting the calls of daily practice. His instructions both in the wards and in the lecture theatre were marked with particular attention to common surgical ailments, and he brought out this side of his teaching well in a manual written in 1928 entitled "Clinical Surgery for Junior Students." His published records of operative work displayed its all-round character and high technical skill, while in his war service he was found to be particularly successful in orthopaedic surgery during his attachment to the Edinburgh war hospital at Bangour and the 2nd Scottish General Hospital at Graigleith. In the *International Journal of Surgery* he wrote of the surgical lessons learned during the war. His professional distinction was realised by his position in

the Royal College of Surgeons of Edinburgh, by his honorary fellowship of the Royal College of Physicians of Edinburgh, and by the LL.D. degree given to him by the University on its 350th anniversary, while at the time of his death he was Manager of the Edinburgh Royal Infirmary.

We quote the following tribute from one of his colleagues: "To those who had the privilege of knowing Dowden intimately, his personality, his upright character, and his vitality made a strong appeal. In him they possessed a loyal and genuine friend who had many attractive qualities: a kindly and sympathetic nature; a whole-hearted infectious enthusiasm for work and recreation; a genial humour, free from any suggestion of cynicism or satire, illuminating his faculty and facility as a story-teller."

Outside his professional interest Dowden was remarkable for the regard in which he held his old school of Merchiston. He was for a long period on the governing body and was at the time of his death chairman. He was mainly instrumental in bringing to a successful issue a scheme for transferring the school from Merchiston Castle to its present site at Colinton. As a young man he had been a prominent sportsman representing his school and university both in cricket and football, while in later life his holidays were devoted to angling.

Mr. Dowden married in 1907 Edith Georgina, daughter of the late Surgeon-General H. R. Oswald, and she survives him.

**HENRY JOHN BANKS-DAVIS, M.B. Camb.,
F.R.C.P. Lond.**

WE regret to announce the death of Mr. Banks-Davis, well known as otologist and laryngologist, which occurred on March 5th at his London address.

Henry John Banks-Davis was the son of the distinguished artist and Academician, H. W. B. Davis, and was born in 1867. He was educated partly in France and partly at Marlborough and entered Trinity College, Cambridge, where he graduated in arts in 1888. He proceeded to St. Thomas's Hospital, took the medical degrees of M.B., B.Ch. in 1895, and served in the hospital as house surgeon and for a time as demonstrator of practical surgery in the medical school. For a time he was resident medical officer to the West London Hospital, and at this period of his career saw considerable post-graduate practice in Paris, Berlin, and Vienna. He then decided to specialise in diseases of the ear and throat. He became chief assistant in the throat and ear department of the Middlesex Hospital and in 1904 was appointed surgeon to the throat, nose, and ear department of the West London Hospital, having been originally elected as assistant physician. His scientific attainments as well as his sympathetic personality soon obtained for him a considerable practice, while contributions of a practical nature to medical journals and to the *Proceedings* of the Royal Society of Medicine confirmed his expert position. In 1912 he was elected F.R.C.P. Lond. His military services were varied and extensive. Some 40 years ago he acted as surgeon to the national fund of the Red Cross in the Greeco-Turkish war and received from the King of the Hellenes the order of the Redeemer of Greece; in the South African war he did useful work to the invalided soldiers and nurses as a member of committees administering funds for those purposes; and during the recent war he held appointments in

several hospitals receiving injured naval officers, where he maintained a high position as a specialist. He had a wide reputation outside his own country due to his frequent selection as a delegate for Cambridge University to international conferences, attending in this capacity conferences on laryngology and otology in Boston, Vienna, and Berlin. He was aural referee to the Civil Service at the time of his death, and had been president of the otological and laryngological sections of the Royal Society of Medicine.

A personal friend writes: "Banks-Davis was appointed to the West London Hospital as assistant physician but relinquished the post to take up work in the ear, nose, and throat department in the days when such work was not regarded as so definitely surgical as it now is; he was assistant to Dr. J. Barry Ball, the physician on the staff of the hospital who had charge of the department, and he succeeded him.

His enthusiasm for his specialty, kindly treatment of the patients, and uniform courtesy combined to build up a large clinic to the great benefit of the hospital. His lectures to the post-graduate college were well attended and much appreciated. He held no other hospital appointment, and was able to devote the whole of his energies to the West London which he served so well. Banks-Davis never married. Once, when I asked him why, he replied that he was wedded to his profession. Conservative by nature he was a man of settled habits. At college he had been a prominent oar. He was a keen fisherman and delighted in salmon-fishing on the Wye, a sport in which he was very proficient, while he had a property in Wales to which he was very attached. With Banks-Davis a friendship once formed was ever loyal and unswerving. He was a man of outstanding personality and gifted with charm and a subtle sense of humour."

MEDICAL NEWS

University of Oxford

An election of two members of the board of the faculty of medicine of this university will be held on June 5th. Nominations must be signed by six members of the general medical electorate and reach the secretary of faculties at the University Registry, Oxford, before May 15th.

University of Birmingham

It is announced that an anonymous donor has placed considerable funds at the disposal of the University for an investigation by Prof. W. N. Haworth, F.R.S., head of the department of chemistry, into the possibility of producing an improved form of insulin.

During the summer term five William Withering lectures will be given on the chemical and biological aspects of immunology. On April 30th, May 14th and 28th Prof. W. W. C. Topley, F.R.S., will speak and on May 7th and 21st Mr. Percival Hartley, D.Sc. The Ingleby lectures will be given this year on May 20th and 22nd by Dr. Walter Schiller, pathologist to the Frauenklinik of the University of Vienna, who will speak on ovarian tumours (granulosa-cell, Brenner, and a new variety, mesonephroma ovarii). He is taking the place of Prof. Frankl who is unable to come as arranged. Prof. Arvid Wallgren, physician-in-chief to the Children's Hospital at Göteborg, has been appointed Ingleby lecturer for 1937. All these lectures will be given at 4 p.m. in the University.

Post-graduate courses in neurology will be held from May to July and in industrial hygiene and industrial medicine from July 13th to 24th. Further information may be had from the dean of the medical faculty.

International Cancer Congress

The Second International Congress of the Scientific and Social Campaign against Cancer will be held in Brussels from Sept. 20th-26th, under the patronage of the King of the Belgians and Queen Elizabeth. The national executive committee of the Congress consists of Dr. Lerat (chairman), Profs. Delrez, Dustin, Goormaghtigh, and Maisin (directors of the anti-cancer centres of Liège, Brussels, Ghent, and Louvain respectively), Dr. Sluys, Dr. Timbal (director-general of the Government Department of Hygiene), Mr. H. Marchal, and Mr. W. Schraenen (general secretary of the Congress).

The programme has been divided into two main parts, embracing the scientific campaign and the social campaign against cancer. In the first part the subjects on which official reports will be prepared and upon which individual communications are invited are grouped together under the following headings: experimental investigation (including the study of predisposing factors); diagnosis; and treatment. In the second part, on the social campaign against cancer, the subjects dealt with are: access of patients to diagnosis and treatment; medico-social assistance to incurable cases; and cancer and demography, including statistics and racial incidence. The list

of official rapporteurs is not yet complete, but among those who have agreed to present reports are: M. Borst, J. W. Cook, W. Cramer, H. F. Deelman, L. Dublin, A. P. Dustin, J. Ewing, W. E. Gye, H. Holthusen, E. L. Kennaway, J. Maisin, M. Nagayo, F. Pentimalli, Cl. Regaud, P. del Rio Hortega, G. Roussy, C. Rowntree, H. Schinz, and F. Carter Wood.

Further particulars may be had from Mr. W. Schraenen at 13, rue de la Presse, Brussels, Belgium.

Public Analysts and Other Analytical Chemists

Although the Society of Public Analysts (since widened to include other analytical chemists) was founded in 1875, two original members—Dr. Bernard Dyer and Dr. J. A. Voelcker—were present at the annual dinner on March 6th and responded to the informal toast of their healths. Mr. John Evans, M.Sc., who presided, proposed the toast of H.M. Ministers to which Sir Kingsley Wood responded, remarking that the first Minister of Health in history seemed to have been Moses, who issued wise enactments for the bodily well-being of the Israelites. Sir Kingsley thought that the responsibility of Ministers was increasing and among them the public health service was of prime importance as a defence and insurance against ill-health. Referring to food which came within the scope of the society's work, 25 million tons a year, he said, were consumed, and it was necessary that nothing should be added to or taken from it, which might lower its quality. The public analysts were the chief defenders of the people's food; the burden laid on them was increasing, but although he had much to do with their work he took no part in their remuneration. The Public Prosecutor, Sir E. Tyndal Atkinson, in proposing the health of the Society, referred to the complicated problems analysts had to solve, both as to what foods should be and in finding out what they were. He spoke with appreciation of the work of the president elect, Dr. Roche Lynch, and said how much the problems of food analysis had changed since Frederick Accum wrote his book on food adulteration some hundred years ago, when bakers, brewers, and druggists were engaged in a vicious circle of poisoning one another with their respective products. The President, in replying, spoke of the many branches of analytical work, instancing the compendious knowledge of the editor of the *Analyst*, Dr. C. Ainsworth Mitchell, who was present as president of the Medico-Legal Society and was an authority on such things as the detection of forgery and the examination of inks. The toast of Kindred Societies, proposed by Mr. Edward Hinks, a past-president, was responded to by Dr. R. H. Pickard, F.R.S., president of the Institute of Chemistry, and Dr. E. Mellanby, secretary of the Medical Research Council, who described himself as, at heart, a laboratory worker. The Master Cutler, Sir Samuel Roberts, a fellow citizen of the President, and Sir Harry Lindsay, director of the Imperial Institute, responded for the Guests, a toast proposed by Prof. W. H. Roberts.

Post-graduate Work in Aberdeen

A course devoted to endocrinology will be held at Marischal College, the Royal Infirmary, and the Royal Hospital for Sick Children, Aberdeen, from April 21st to June 18th. The lectures and demonstrations will be given at 3.15 p.m. on Tuesdays and repeated at the same time on Thursdays. Applications should reach the secretary of the University not later than April 15th.

Royal Society of Arts

The Thomas Gray prize of £100 for an invention "considered to be an advancement in the science or practice of navigation" has been divided between Mr. H. J. Buchanan-Wollaston, for his current meter, and Dr. F. W. Edridge-Green, F.R.C.S., for his colour perception lantern. The latter is an improved form of the Edridge-Green lantern used in the Navy and mercantile marine, and by railways, for ascertaining defects in colour perception.

Belt Memorial Fellowships

An election of junior fellows will take place in July. The fellowships are normally of the annual value of £400 and are usually tenable for three years. Some preference will be given to candidates proposing researches in mental diseases. Candidates should be prepared to begin work on Oct. 1st, and applications should be sent to Prof. T. R. Elliott, F.R.S., University College Hospital medical school, London, W.C.1.

Oto-rhinology in Austria

A second congress of Austrian ear, nose, and throat specialists will be held at Graz on June 12th and 13th. The principal subjects for discussion will be conservative and operative treatment of suppuration in the frontal sinuses and of laryngeal stenosis, metabolic disturbance in relation to diseases of the ear and the operative treatment of chronic suppurative otitis media. Further information may be had from Ernst Urbantschitsch, Schottenring 24, Vienna 1.

Incorporated Society of Chiropodists

The annual convention of this society will be held at the Langham Hotel, Portland-place, London, W., on Friday and Saturday, March 20th and 21st. During the course of the meeting lectures will be given by Dr. H. W. C. Vines (bacterial virulence), Mr. C. Lambrinudi (mechanical disabilities of the foot), and Mr. T. Pomfret Kilner (the scope of plastic and reconstructive surgery). Further information may be had from the secretary of the society, 21, Cavendish-square, London, W.1.

University of London Animal Welfare Society

On Tuesday, March 17th, at 8 p.m., at Birkbeck College, Breams Buildings, London, E.C., Prof. Walter Garstang, emeritus professor of zoology in the University of Leeds, will speak on the songs of birds. The lecture will be illustrated by gramophone and other instruments. Admission is free, without ticket.

The Sir Charles Hastings Lecture

This lecture was delivered on Tuesday evening in the hall of the British Medical Association by Prof. Winifred Cullis, the title being "Keeping Fit." Dr. R. Cove-Smith followed with a joint address on the same subject. Prof. Cullis discussing particularly the diet of children said that in artificially fed babies 70 per cent. were found recently to suffer from lack of vitamin C and iron, and added, speaking generally, that the diet of children should be varied but moderate, while every child should have at least a pint of milk a day. Dr. Cove-Smith was drastic in his criticism of modern habits. He regarded tobacco and alcohol as drugs and therefore not to be used indiscriminately; he described much restaurant food as "twice cooked mush"; he pointed to the risk to young people of dancing late into the night in overcrowded rooms from which they emerged inadequately clothed; he pointed out that the frequent use of baths at too high a temperature had its perils; and he coupled a commendation of the open-necked fashions in women's clothes with a denunciation of the too tight collar worn by many men. The chair was taken by Dr. Adolphe Abrahams, consulting medical adviser to the British Olympic athletic team, and both the deliveries making up jointly the Hastings lecture were vigorous and practical.

Mental After-Care Association

The annual meeting of this association will be held at the Stationers' Hall, Ludgate Hill, London, E.C., on Wednesday, March 18th, at 3 p.m., when the speakers will include Sir Hubert Bond, Dr. G. W. B. James, Dr. W. D. Nicol, Dr. J. F. E. Prideaux, and Dr. Reginald Worth.

King's College Hospital

A petition is to be presented to The King to continue the patronage to the hospital granted by previous sovereigns. Progress is being made here with the new nurses' home and private patients block. Expenditure last year had been very heavy and but for the exceptionally large legacies received during the year the deficit would have been much greater.

A Birmingham Welfare Centre

On Feb. 24th Mrs. W. A. Cadbury opened a new centre to extend the work of the public health, maternity and child welfare committee among the hundreds of families living on the Weoley Castle estate, Birmingham. At the new centre there are facilities for light meals and a class-room for instruction in cooking and nursery work.

Medical Diary

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, March 17th.

General Meeting of Fellows. 5.30 P.M.

Pathology. 8.15 P.M. for 8.30 P.M. Annual General Meeting. L. B. Holt: The Antitoxin Response to Varying Doses of Staphylococcus Toxoid. J. Patterson: The Quantitative van den Bergh Reaction and the Separate Evaluation of the Two Types of Pigment when present together in Serum. J. B. Duguid: Histogenesis of Experimental Tubular Nephritis. D. M. Pryce: Case of Tuberculous Arteritis. E. Hardy: Pneumococcal Septicæmia with Organisms in the Blood Film. A. B. Rosher: Streptothrix Morphologically Resembling *C. diphtheriæ*. B. H. E. Cadness: Case of Sickle-cell Anæmia.

THURSDAY.

Dermatology. 5 P.M. (Cases at 4 P.M.) Dr. H. W. Barber: 1. Leiomomata. Dr. G. B. Dowling: 2. Fox-Fordyce Disease. Dr. J. E. M. Wigley: 3. Pustular Psoriasis. Dr. J. Twiston Davies: 4. Case for Diagnosis: ? Kyrle's Disease. Dr. R. Klüber and Dr. Preudenthal: 5. Sections from Two Cases of Blue Nævi (Jadassohn). Dr. I. Muende: 6. Pringle's Adenoma Sebaceum. 7. Lichen Planus Simulating Pityriasis Rosea. Dr. G. Bamber: 8. Telangiectasia Hereditaria Hæmorrhagica. Dr. R. T. Brain: 9. Dermatolysis and Nævus Pigmentosus. 10. Urticaria Pigmentosa Dating from Birth.

Neurology. 8 P.M. Mr. Geoffrey Jefferson: Compressions of the Chiasma, Optic Nerves and Optic Tracts by Intracranial Aneurysms. Film (made by Dr. H. L. Gordon in Kenya) of Huntington's Chorea will be shown by Dr. C. Worster-Drought.

FRIDAY.

Radiology. 8.15 P.M. Report of the council of the section making recommendations to the General Medical Council as to the place of radiology in the medical curriculum. Dr. E. W. Twining and Mr. Hugh Cairns: Value of Radiology in Neurosurgery. Dr. M. H. Jupe, Mr. G. Jefferson, Mr. D. W. Northfield, and Dr. J. Purdon Martin will also speak.

HUNTERIAN SOCIETY.

MONDAY, March 16th.—8.30 P.M. (Simpson's Restaurant, Bird-in-Hand Court, 76, Cheapside), Dr. Adolphe Abrahams, Dr. C. S. Myers, F.R.S., and Dr. J. C. Bridgè: Fatigue.

ROYAL MICROSCOPICAL SOCIETY.

WEDNESDAY, March 18th.—4.30 P.M. (London School of Hygiene, Koppel-street, W.C.), Joint Discussion with Food Group of the Society of Chemical Industry on the Microscopy of Foods.

CHELSEA CLINICAL SOCIETY.

TUESDAY, March 17th.—8.30 P.M. (Hotel Rembrandt, Thurloe-place, S.W.), Mr. Hugh Cairns: Modern Cranial Surgery.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, Manson House, 26, Portland-place, W.

THURSDAY, March 19th.—8.15 P.M. (Royal Army Medical College, Grosvenor-road, Millbank, S.W.), Laboratory Meeting.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Thornhaugh-street, W.C.

FRIDAY, March 20th.—5.30 P.M., Prof. S. J. Cowell and Dr. G. C. M. McGonigle: Nutritional Factors in the Prevention of Disease.

Maternity and Child Welfare Group.—8.30 P.M., Dr. Eric Pritchard: Neonatal Mortality, its Causes, Prevention, and Treatment. Dr. Virginia Saunders-Jacobs will also speak.

EUGENICS SOCIETY.

TUESDAY, March 17th.—5.15 P.M. (Rooms of the Linnean Society, Burlington House, Piccadilly, W.), Mr. D. Caradog Jones: Eugenics and the Merseyside Inquiry.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.
TUESDAY, March 17th, and THURSDAY.—5 P.M., Dr. John Parkinson: Enlargement of the Heart. (Lumleian Lecture.)

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.
MONDAY, March 16th.—5 P.M., Dr. L. W. Proger: Specimens illustrating Tumours of the Kidney.

FRIDAY.—5 P.M., Dr. A. J. E. Cave: The Anatomy of Certain Vertebral Joints.

ROYAL INSTITUTION, 21, Albemarle-street, W.
TUESDAY, March 17th.—5.15 P.M., Prof. Edward Mellanby, F.R.S.: Drug-like Actions of some Foods.

INSTITUTE OF HYGIENE, 28, Portland-place, W.1.
WEDNESDAY, March 18th.—3.30 P.M., Dr. G. W. Theobald: Some Effects of Emancipation on the Health of Women.

CHADWICK PUBLIC LECTURE.
THURSDAY, March 19th.—5.30 P.M. (Royal United Service Institution, Whitehall, S.W.), Dr. Arthur MacNalty: Epidemic Poliomyelitis.

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane-road, W.
MONDAY, March 16th.—2.30 P.M., Dr. Gordon Holmes: Cerebro-spinal Syphilis. 3.30 P.M., Prof. F. J. Browne: Toxæmias of Pregnancy.

TUESDAY.—2.30 P.M., Dr. Leonard Colebrook: Puerperal Sepsis. 2.30 P.M., Dr. Janet Vaughan: Tests for Pregnancy.

WEDNESDAY.—Noon, Clinical and pathological conference (medical). 2.30 P.M., Clinical and pathological conference (surgical). 3.30 P.M., Mr. Aleck Bourne: Disproportion and Difficult Labour.

THURSDAY.—2.15 P.M., Dr. Duncan White: Radiological Demonstration.

FRIDAY.—3.30 P.M., Dr. R. E. Roberts: Radiology in Obstetrics. 5 P.M., Sir James Walton: The Surgical Aspects of Dyspepsia.

Medical clinics, surgical clinics or operations, obstetric and gynaecological clinics or operations daily from 10 A.M. to 4 P.M.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, March 16th, to SUNDAY, March 22nd.—ROYAL NATIONAL ORTHOPEDIC HOSPITAL, Great Portland-street, W. Post-graduate course in orthopaedics.—INFANTS HOSPITAL, Vincent-square, S.W. Mon., Wed. and Fri., 8 P.M., primary F.R.C.S. course in anatomy and physiology.—BROMPTON HOSPITAL, S.W. Mon., Tues., Wed., and Thurs., 5 P.M., special M.R.C.P. class.—ROYAL CHEST HOSPITAL, City-road, E.C. Mon., Wed., and Fri., 8 P.M., special M.R.C.P. class in chest and heart diseases.—MILLER GENERAL HOSPITAL, Greenwich-road S.E. Week-end course in general medicine.—Courses are open only to members of the Fellowship.

PRINCESS BEATRICE HOSPITAL, Richmond-road, S.W.
THURSDAY, March 19th.—8.45 P.M., Dr. B. Buckley Sharp: Demonstration of Cases. Mr. Kenneth Heritage: The Treatment of Prostatic Obstruction. Mr. A. Lawrence Abel: The Pavex Treatment of Vascular Disease. Mr. Abel: Surgical Travels in North America, illustrated by cinematograph films.

NATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, March 16th.—3.30 P.M., Dr. Symonds: Head Injuries (II.).

TUESDAY.—3.30 P.M., Dr. Grainger Stewart: Meningitis and Cerebral Abscess.

WEDNESDAY.—3.30 P.M., Dr. Kinnier Wilson: Clinical Demonstration.

THURSDAY.—3.30 P.M., Dr. Riddoch: Cerebral Tumours.

FRIDAY.—3.30 P.M., Dr. Denny-Brown: Neuritis. Out-patient clinic daily at 2 P.M.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL, N.W.
WEDNESDAY, March 18th.—1 P.M., Mr. A. Sorsby: The Ophthalmoscope in Cardiovascular Disturbances.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
WEDNESDAY, March 18th.—2 P.M., Dr. Reginald Lightwood: Survey of Pulmonary Tubercle. 3 P.M., Dr. A. Signy: The Value of the Mantoux Test.

Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M.

ST. JOHN CLINIC, Ranelagh-road, S.W.
FRIDAY, March 20th.—1.30 P.M., Demonstration of Chest Remedial Exercises for Asthma, Remedial Exercises for Sciatica, Rheumatic Diseases.

LEEDS GENERAL INFIRMARY.
TUESDAY, March 17th.—3.30 P.M., Dr. Cooper: Recent Developments in X Ray Therapy.

MANCHESTER ROYAL INFIRMARY.
TUESDAY, March 17th.—4.15 P.M., Mr. Harry Platt: Common Disabilities of the Foot.

FRIDAY.—4.15 P.M., Dr. C. S. D. Don: Demonstration of Medical Cases.

UNIVERSITY OF DURHAM.
SUNDAY, March 22nd.—10.30 A.M. (Newcastle General Hospital), Dr. E. B. Wright: Selected Cases.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION
WEDNESDAY, March 18th.—4.15 P.M. (Ophthalmic Institution), Dr. T. Stewart Barrie: The Red Eye.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 29TH, 1936

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2386; diphtheria, 1200; enteric fever, 29; acute pneumonia (primary or influenzal), 1529; puerperal fever, 41; puerperal pyrexia, 126; cerebrospinal fever, 35; acute poliomyelitis, 5; acute poliomyelitis, 1; encephalitis lethargica, 4; dysentery, 77; ophthalmia neonatorum, 96. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on March 6th was 5194, which included: Scarlet fever, 968; diphtheria, 1033; measles, 1774; whooping-cough, 704; puerperal fever, 18 mothers (plus 14 babies); encephalitis lethargica, 283; poliomyelitis, 4. At St. Margaret's Hospital there were 25 babies (plus 13 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 2 (0) from enteric fever, 88 (20) from measles, 6 (0) from scarlet fever, 45 (10) from whooping-cough, 40 (6) from diphtheria, 68 (23) from diarrhoea and enteritis under two years, and 107 (17) from influenza. The figures in parentheses are those for London itself.

The mortality from influenza has varied but little during the present year, the total deaths for the last 13 weeks (working backwards) being 107, 119, 97, 85, 98, 104, 89, 110, 110, 80, 67, 62, 45. The deaths this week are scattered over 53 great towns, Birmingham reporting 9, Manchester 7, Croydon 5, no other great town more than 3. Liverpool reported 11 deaths from measles, Manchester 9, Salford 7, Birkenhead and Sheffield each 5, Bristol 4. Liverpool also reported 8 deaths from whooping-cough, Manchester and Birmingham each 5. Deaths from diphtheria were reported from 24 great towns: 5 from Manchester, 3 from Bradford, 2 each from Ilford, Leyton, Hull, West Hartlepool, and Birmingham.

The number of stillbirths notified during the week was 296 (corresponding to a rate of 45 per 1000 total births), including 52 in London.

Births, Marriages, and Deaths

BIRTHS

DEIGHTON.—On March 5th, at Cleethorpes, the wife of Dr. A. H. Deighton, of a son.

GIBSON.—On March 3rd, at Torquay, the wife of Paul C. Gibson, M.D. Lond., Torquay, of a son.

GLANVILLE.—On March 1st, at Devonshire-place, W., the wife of Dr. Reginald Glanville, Windsor Forest, Berks, of a daughter.

HALLEY.—On March 7th, at Ascot, the wife of G. Stiven Halley, M.D. St. And., of a son.

MARRACK.—On March 8th, at Bishop's Stortford, the wife of John Marrack, M.D. Camb., of a son.

PRYCE.—On March 3rd, at Welbeck-street, W., the wife of Dr. D. Merlin Pryce, of a daughter.

RHYS-JONES.—On March 3rd, the wife of Dr. Gwilym C. Rhys-Jones, of Dartford, of a son.

UPJOHN.—On March 4th, at Haverhill, Suffolk, to Dr. Margaret Carnegie Simpson, wife of F. H. Upjohn—a son.

MARRIAGES

JOLL—RAMSDEN.—On Feb. 29th, at St. George's, Hanover-square, Cecil A. Joll, M.S. Lond., F.R.C.S. Eng., of Harley-street, W., to Antonia (Toni), younger daughter of Mr. F. H. Ramsden, of Cambridge-terrace, W.

DEATHS

BANKS-DAVIS.—On March 5th, at Portman-street, W., Henry John Banks-Davis, M.B. Camb., F.R.C.P. Lond.

CLARKE.—On March 5th, at St. Albans, of pneumonia, Sidney Herbert Clarke, M.D. Camb.

CRAIG.—On March 8th, suddenly, at Littlehampton, Daniel Craig, M.D. Glasg.

DAVIS.—On March 3rd, at Brighton, Ivor Davis, M.D. Durh.

DOWDEN.—On March 3, at Edinburgh, John Wheeler Dowden, LL.D., F.R.C.S. Edin.

GIBBENS.—On March 1st, at Barking, Essex, Frank Edward Gibbens, M.R.C.S. Eng.

MAGILL.—On March 9th, at a nursing home in London, Sir James Magill, K.C.B., M.D., M.S., Q.V. Irel., M.R.C.S. Eng., Col., late R.A.M.C.

MENZIES.—On March 7th, at Farnborough, Henry Menzies, M.B. Camb., of Hobart-place, S.W.

SHEARER.—On March 7th, suddenly, Thomas Pitcairn Shearer, L.R.C.P. Edin., of Leicester, in his 79th year.

THOMSON.—On Feb. 27th, at Menton, Brevet-Col. Samuel John Thomson, C.I.E., C.B.E., I.M.S.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

PAINLESS DENTISTRY

A FEW weeks ago a report was widely circulated in the lay press announcing the discovery by Dr. Leroy Hartman, of Columbia University, of a sensitising solution by means of which the preparation of carious teeth for filling could be made painless in a few moments. It may be permitted to discount the somewhat sensational way in which the announcement was made and to believe that Dr. Hartman, who is a well-known dental surgeon in America, was not responsible for the flamboyant terms in which his discovery was made public. The solution consisted of thymol $1\frac{1}{2}$ parts, ether 2 parts, and 95 per cent. pure ethyl alcohol 1 part. The solution should be applied with cotton-wool to the dentine of the tooth to be filled and allowed to remain for $1\frac{1}{2}$ minutes for adults. It was claimed that this made the cavity preparation genuinely painless. We learn from newspaper reports that an unprecedented rush on chemists by American dentists has caused the supply of thymol to run short.

No doubt in this country many dental surgeons have felt it their duty to try this method, for although the manner of its announcement was not entirely calculated to dispel doubt, it would have been foolish to neglect any method which might render the use of the dental engine less unpleasant. Several letters have appeared in succeeding issues of the *British Dental Journal* which show that many have given Hartman's solution a trial with results on the whole unsatisfactory, though some have recorded successes. The varying results suggest that the psychical factor may not have been entirely absent, for there is no doubt that many patients are extremely suggestible where pain is concerned. An announcement that the marvellous new drug, guaranteed to make dentistry painless, was about to be tried, would doubtless be sufficient in many cases to make the patients believe that it was as effective in their case.

Topical applications to a carious cavity before cutting it out have long been used by dental surgeons and various drugs alone or in combination have been employed. The composition of Hartman's solution suggests that it may act by producing cold in the tooth. In so far as it does this there is no doubt that it would reduce pain. But it may be said of all drugs or preparations known to the dental profession that none of them can be relied upon to act as obtundents in every case. One of the best ways of making cavity preparation comparatively painless is by spraying a fine jet of cold water on the tooth to be prepared. In many cases, though not all, this will make a tooth so insensitive that it is possible to cut out the cavity without pain. Its disadvantage is that it requires the services of an assistant and is not very easily applied to back teeth.

Paraform, a polymer of formaldehyde, is a valuable obtundent. A minute quantity sealed in a carious cavity for a few days is often effective in reducing the sensitiveness. But it is a highly irritating drug and must be used with caution in case it brings about death of the dental pulp. For this reason it can only be used in shallow cavities. Eugenol, phenol, ethyl chloride as topical applications are all among the methods in use. They may have a temporary effect, always transient and frequently disappointing.

A local injection as used for the extraction of teeth is one of the best methods of rendering cavity preparation painless; but the anaesthesia may take some time to develop. A good result can usually be promised for front teeth, but for the molars the results are so variable as to rob this method of a good deal of its value. There is a natural tendency on the part of some patients to think that specific methods to relieve pain must be effective and that if they are not, the fault may be that of the dentist. While painless dentistry is still an ideal much can be done to diminish the pain attendant on the process of

filling teeth. Drugs have their place, but it still remains true that sharp instruments, a gentle touch, a sympathetic manner, and a clear knowledge of what has to be done are perhaps the most effective methods known to dentists of making conservative dentistry as little unpleasant as possible to the patient.

MORAL PROBLEMS IN HOSPITAL PRACTICE
BY ROMAN CATHOLICS

A WORK¹ which has the *Imprimi Potest* the *Nihil Obstat* and the *Imprimatur* of various Roman Catholic episcopal authorities is written for sisters in charge of hospitals who may at times be placed in sudden and grave doubts about the moral legitimacy of certain surgical operations. "The cases giving rise to these doubts," says the author, "are very often urgent cases and they not infrequently involve questions of life and death, and hence call for an immediate decision which the Sister finds it impossible to give in existing circumstances."

The conduct which is enjoined upon hospital sisters by Father Finney certainly may involve questions of what can broadly be described as hospital discipline. Thus, we are told that it is never lawful, even for medical or therapeutic reasons, to produce direct abortion, and that it is unlawful to sterilise a woman whose reproductive organs are normal but whose life might be threatened by diseases of other organs such as the heart, lungs, or kidneys, if she were to become pregnant. The book is written in the form of a series of questions and answers, the moral basis of which are expounded.

Q. 54.—"Has a Sister in charge of an operating-room the right to question a surgeon, as to the purpose of the work he is doing, in the course of an abdominal operation?" A.—"Yes, she has not only the right, but it is also her duty to question him, if she has reasonable grounds to suspect that he is doing something that is not morally lawful."

Q. 55.—"Has a Sister the right to question the surgeon, or tell him not to remove ovaries, or to do a complete hysterectomy?" A.—"Ordinarily a Sister has no right to tell a surgeon not to remove ovaries, or to do a complete hysterectomy, because if these organs are at all diseased, the surgeon must be the sole judge of what is to be done regarding their removal. However, if these organs are evidently healthy, and a Sister has reasonable grounds for suspecting that the surgeon is removing them for the purpose of sterilising the patient, the Sister has not only the right but the duty to question him."

Q. 56.—"If curettage is slated on the board, how is the Sister to know whether it is for the purpose of abortion or not?" A.—"This question is best answered by stating that a Sister in charge of an operating-room has a right to know, in advance, the exact nature of each operation that is to be performed. Therefore it should be an established rule, not only with regard to curettage, but with regard to any other operation, that a surgeon should state in advance to the Sister in charge of the operating-room the nature of the operation he intends to perform, at least as far as his diagnosis will enable him to do so."

In view of the fact that the views of the Roman Catholic church concerning the conditions which justify termination of pregnancy and sterilisation do not always harmonise with those which govern orthodox medical practice, it is possible to envisage that a difficult situation might arise in the course of an operation if Roman Catholic hospital sisters were invariably to perform their moral duty as specified in this book. The divergences of Roman Catholic moral teaching from orthodox medical

¹ Moral Problems in Hospital Practice. A Practical Handbook. Fifth edition. By the Rev. Patrick A. Finney, C.M.I., University of Dallas. London: B. Herder Book Company, 1935. Pp. 208. 6s.

teaching can be illustrated by the following questions and answers:—

Q. 8.—“If it is morally certain that a pregnant mother and her unborn child will both die, if the pregnancy is allowed to take its course, but, at the same time, the attending physician is morally certain that he can save the mother's life by removing the inviable fetus, is it lawful for him to do so?” A.—“No, it is not. Such a removal of the fetus would be direct abortion.”

Q. 34.—“In a case of ectopic pregnancy, in which the presence of the fetus is regarded as endangering the mother's life, is it lawful to remove an inviable ectopic fetus?” A.—“No, it is not lawful.”

A hospital sister's duties with regard to extraction of the fetus after the death of the mother and baptism may also be found surprising. They are governed by a principle stated by Dr. Austin O'Malley in the following words:—

“When we began to vegetate, our life began; we had a soul; and this as soon as the pronucleus of the spermatozoon fused with the pronucleus of the ovum, and made the first segmentation-nucleus. Before the first fission of that segmentation nucleus was completed into two distinct cells the soul was present, for that fission was independent life; and any life is impossible without a soul, or, what is the same thing, a vital principle. Since, moreover, the soul with the body is man, and since the process of vegetation in our present state is identical with that first cell-fission, this splitting primordial cell is a human being. The active primordial cell in this stage is as much a complete phase of human life as are the body and soul of a person at puberty, or at adult age.”

It follows from this statement that “if a mother dies during pregnancy, the fetus should be extracted by those upon whom this duty devolves.” . . . “The human embryo is distinguishable and has the form of a fetus as early as the end of the fourth week of gestation.”

This fourth provision of the canon is based upon the fact that the fetus often survives the mother who dies before delivery, and therefore nothing should be left undone to extract the fetus without delay, because, under the circumstances, there is nearly always a chance to administer baptism, and thereby secure eternal life for the fetus, and, in cases where the fetus has reached the term of viability, there is also a chance to preserve its temporal life. Regarding the operation for the extraction of the fetus, Father Ferreres writes as follows:—

“Since cases of apparent death are not uncommon in pregnant women, and since it is important—in order to secure the fetus alive—that the cesarean operation should take place as soon as possible, two points are to be borne in mind: (1) that there be certainty of the mother's death; (2) that the cesarean operation, or any other operation deemed necessary, be performed with the same caution and care as in the case of a living mother, so that, if alive, she may not be killed, as unfortunately has taken place more than once.” (“Death Real and Apparent,” pp. 38-39.)

The duty is also imposed of baptising an unborn child. The following instructions are given:—

Use a syringe which has been rendered aseptic and fill it with boiled water. If the membranes have not broken, they must be ruptured and the amniotic fluid discharged. The syringe is then carefully inserted in the vagina, and the water directed against the child's head, while at the same time you say the form of baptism. Do this without hurry, and be careful not to injure the parts. The water should be boiled and cooled to the temperature of the body before use. If the syringe is aseptic and the water boiled, there will be no danger of infecting the mother. If the os uteri be only partially dilated, it will be better to eject the water during “a pain.” If the os uteri be undilated, a valid baptism is practically impossible. As there is always a doubt with regard to the validity of intra-uterine baptism, in practice you should baptize again conditionally after it is born, pouring water on the

child's head and saying, “If thou are not baptized, I baptize thee in the Name of the Father, and of the Son, and of the Holy Ghost.” If the child's head is born, but not the rest of the body, and death is feared, you will baptize in the ordinary way, and conditional baptism will not be required afterwards. The umbilical cord is only a temporary part of the child, and baptism performed upon it is certainly invalid.

Difficulties may, however, arise as to the sister's duty in the event of an early miscarriage. The following instructions given by the Rev. John Fletcher are quoted by the author as authoritative:—

“If, however, the immature product of conception be passed, the question—and the most difficult question—is to determine whether it be living or dead. As every embryo has a rational soul, it follows that every fetus, prematurely expelled from the womb, should be baptized, if living; baptized conditionally (‘if thou are alive,’ etc.) if life be uncertain, and left alone if certainly dead. Make sure that what is passed is an embryo before you baptize it conditionally. Do not try and give the Sacrament to a large, decomposed blood clot, for instance. The ovum varies in size according to its age, and is generally covered with its membranes when expelled. If passed covered with the membranes, these must be quickly opened, and the fetus baptized conditionally. If small, it may be baptized by immersion. Place it in a small bowl of water, rupture the membranes with your thumb and forefinger, and at the same time say, ‘If thou art alive, I baptize thee,’ etc., and take it immediately out of the water. The advantage of this method is that you lose no time, and you have not to search for the head. With regard to abnormal fruits of conception, these misfortunes are fortunately very rare and die soon after birth. If they possess a head and breast, they should be baptized. Unless there be immediate danger of death, leave the question of baptism to the priest.”

In addition to the above, the Rev. John Fletcher, from whom Father Patrick Finney here quotes gives the following note:—

“In cases of intra-uterine baptism, by a decree of the Sacred Office, August 21, 1901, a solution of one part bichloride of mercury in 1000 parts of water is allowed, if the use of plain water would be dangerous to the mother—not unless danger be present. The author, in any case, prefers the boiled water recommended in the text.”

MASQUE OF SPRING

SPRING and its new fashions will be seen together in a “Masque of Spring” to be presented next week in the fashion theatre of Messrs. Derry and Toms of Kensington by a clever company of artistes recruited from Covent Garden and other theatres, who will dance, mime, and parade to incidental music by classic and modern British composers, in three scenes—Morning, Afternoon, and Night. The masque, with expert choreography and designs by Andree Howard, will be an ambitious attempt to present new fashions in an artistic setting, and the Westminster Hospital is indebted to Messrs. Derry and Toms for the generous offer of the proceeds of the first performance.

“SYNTROPAN IN SEA-SICKNESS.”—Several inquiries have reached us about the preparation mentioned by Prof. C. Stanton Hicks in his letter on the treatment of sea-sickness (THE LANCET, Jan. 25th, p. 226). We are informed that this preparation is not actually on the market, but the Hoffmann-La Roche Chemical Works Ltd. (51, Bowes-road, London, N.13) are willing to hand trial supplies free of charge to medical men who are specially interested, and, if need be, are in a position to execute orders from wholesale or retail chemists. The preparation is a combination of Syntropan and Sedormid, the latter being a widely used sedative belonging to the open-chain ureides. Syntropan itself, a synthetic drug primarily intended for the relief of spasm, is obtainable in the ordinary form of oral tablets of 1 c.cm. ampoules.

THE RISK OF DIRT

A NEW poster shortly to be issued by the Health and Cleanliness Council reproduces their slogan "where there's dirt there's danger" in an arresting manner. The secretary of the movement (5, Tavistock-square, London, W.C.) will be pleased to send specimens of the poster free of charge, together with particulars of an offer of supplies of posters for distribution. The affixing of these bills in conspicuous places in certain districts should be of public utility.

Messrs. J. AND A. CHURCHILL LTD. inform us that the London County Council have renumbered the houses in Gloucester-place and that in future all communications about their publications, including The Medical Directory, should be directed to 104, Gloucester-place, W.1.

Appointments

BARNETT, T. S. M., M.D. Melb., F.R.C.S. Eng., has been appointed Visiting Consultant Obstetrician for Portsmouth.
BELL, A. C. H., M.B. Lond., F.R.C.S. Eng., M.C.O.G., Assistant Obstetric Surgeon to the Westminster Hospital.
HUGHES, EDWARD, M.D. Liverp., D.P.H., Deputy Medical Officer of Health for Plymouth.
KERR, J. A., B.Sc. Birm., F.R.C.S. Eng., Hon. Surgeon to the Buchanan Hospital, St. Leonards-on-Sea.
TIPPETT, G. O., M.B. Lond., F.R.C.S. Eng., Surgical Registrar at the London Lock Hospitals.
London Hospital.—The following appointments are announced:
NELSON, H. P., M.D. Camb., F.R.C.S. Eng., Hon. Assistant Surgeon;
BROWN, A. I. PARRY, M.B. Lond., D.A., Hon. Assistant Anaesthetist; and
COOPER, AUSTIN, M.D. Dub., Consulting Anaesthetist.
Queen Charlotte's Maternity Hospital.—The following appointments are announced:
HARBUTT, S. W. J., M.B. N.Z., Senior Resident Medical Officer;
WELLS, C. P. B., M.R.C.S. Eng., Assistant Resident Medical Officer;
KARRAN, C. W. C., M.B. Camb., District Resident Medical Officer;
FORSTER, D. I., M.R.C.S. Eng., Resident Anaesthetist and District Resident Medical Officer; and
OLDFIELD, J. M., M.R.C.S. Eng., Resident Anaesthetist.
Certifying Surgeons under the Factory and Workshop Acts:
DR. J. T. GRASSIE (Cheltenham District, Gloucester);
DR. G. I. GRIFFITHS (Bangor District, Caernarvon); Mrs. E. A. HUGHES, M.D. Lond. (Ruthin District, Denbigh).

Vacancies

For further information refer to the advertisement columns

Aberdeen Royal Infirmary.—Surgical Registrar. £200.
Aberdeen Royal Mental Hospital.—Asst. Physician. £300.
Altrincham General Hospital.—Sen. H.S. At rate of £150.
Aylesbury, Royal Buckinghamshire Hospital.—Second Res. M.O. £150.
Beckenham, Bethlem Royal Hospital, Monks Orchard.—Two Res. H.P.'s. Each £175.
Birmingham, Erdington House.—Deputy M.O. £800.
Birmingham, Little Bromwich Hospital for Infectious Diseases.—Jun. Res. M.O. £300.
Blackburn County Borough.—Asst. M.O.H. and Asst. School M.O. £600.
Bristol City and County, Child Guidance Clinic.—Psychiatrist. At rate of £500. Also Social Worker. £275.
Canterbury, Kent County Mental Hospital, Chartham Down.—Med. Supt. £1000.
Cardiff, King Edward VII. Welsh National Memorial Association.—Res. Asst. Tuber. M.O. £500. Res. M.O. £350. Also Asst. Res. M.O. £200, for Sully Hospital, Glam.
Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. Third Assts. to Out-patient Dept.
Charing Cross Hospital.—Registrar to Nose, Throat, and Ear Dept. £100. Also Hon. Clin. Asst. to Dermatological Dept.
Chelsea Hospital for Women, Arthur-street, S.W.—Surgeon for Ear, Nose, and Throat.
Cheshire, Institution for Mental Defectives, Cranage Hall.—Res. Med. Supt. £800.
Chester, Barrowmore Hall, Great Barrow.—H.P. At rate of £150.
Chester Royal Infirmary.—H.S. £150.
Derby, Brebley Hall Orthopaedic Hospital, near Burton-on-Trent.—Asst. M.O. and Res. H.S. Each at rate of £150.
Devonbury and District General Infirmary.—Second H.S. £150.
Dewsbury, Infectious Diseases Hospital.—Res. M.O. £200.
Durham County Council.—Asst. Welfare M.O. £500.
Eastbourne, Princess Alice Memorial Hospital.—Res. H.S. £150.
Eastbourne Royal Eye Hospital, Pevensey-road.—H.S. £100.
Elizabeth Garrett Anderson Hospital, 144, Euston-road, N.W.—Hon. Clin. Assts. Also Hon. Asst. Obstetrician.

Evelina Hospital for Sick Children, Southwark, S.E.—Dental Surgeon. Also H.S. At rate of £120.
Great Western Railway Medical Fund Society, Swindon.—Chief M.O. £1200.
Great Yarmouth General Hospital.—H.S. £140.
Guildford, Royal Surrey County Hospital.—Res. Surg. O. £250.
Harrow Urban District.—Asst. M.O. £800.
Hospital for Sick Children, Great Ormond-street, W.C.—Res. H.P. and Res. H.S. Each at rate of £100.
Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.—Res. H.S. At rate of £75.
Huddersfield County Borough.—Asst. M.O.H. £500.
Huddersfield Royal Infirmary.—H.P. and Res. Anaesthetist. Also H.S. Each at rate of £150.
Ilford, King George Hospital.—H.P. and two H.S.'s.
Institute of Ray Therapy, Camden-road, N.W.—Part-time M.O. At rate of £100.
Isolation Hospital, Muswell Hill.—Res. M.O. £400.
Kent Education Committee.—Asst. M.O. £500.
Kent and Canterbury Hospital.—Hon. Dermatologist.
King's College Hospital, S.E.—Asst. Surg. and Asst. Orthopaedic Surgeon.
Lancaster County Mental Hospital.—Asst. M.O. £500.
Liverpool Sanatorium, Delamere Forest, Frodsham.—Second Asst. to Med. Supt. £200.
London County Council.—Two Asst. M.O.'s (Grade I). Each £350. Four Asst. M.O.'s (Grade II). Each £250. Also five Temp. District M.O.'s. £300-£100.
London Lock Hospitals.—Two Res. M.O.'s. One for Male Dept. One for Female Dept. Each at rate of £175.
London University.—University Chair of Biochemistry. £1000. Also University Readership in Anatomy. £600.
Macclesfield General Infirmary.—Second H.S. At rate of £150.
Manchester, Ancoats Hospital.—H.S. At rate of £100.
Manchester, Withington Hospital and Institution.—Jun. Asst. M.O. At rate of £200.
Mansfield, Harlow Wood Orthopaedic Hospital.—Two H.S.'s. At rate of £200.
Mount Vernon Hospital, Northwood, Middlesex.—Asst. Radiologist. £350.
Newport, Mon. Royal Gwent Hospital.—Cas. O. At rate of £175. Asst. Cas. O. Also two H.S.'s and H.P. Each at rate of £135.
Northumberland County Council.—Asst. County M.O.H. £500.
Norwich, Jenny Lind Hospital for Children.—Res. M.O. £120.
Nottingham General Hospital.—H.P. At rate of £150.
Paddington Green Children's Hospital, W.—H.P. and H.S. Each at rate of £150.
Plymouth, Prince of Wales's Hospital, Greenbank-road.—H.S. At rate of £120.
Port Said, British Hospital.—Principal M.O. £700.
Preston and County of Lancaster Royal Infirmary.—H.P., Cas. H.S., also H.S. Each at rate of £150.
Princess Beatrice Hospital, Earl's Court, S.W.—Hon. Anaesthetist.
Princess Louise Kensington Hospital for Children, St. Quintin-avenue, W.—Clin. Asst. for Out-patient Dept.
Rochdale Infirmary and Dispensary.—Second H.S. £150.
Rotherham Hospital.—Cas. H.S. £150.
Rotherham, Oakwood Hall Sanatorium.—Asst. Res. M.O. £250.
Royal Chest Hospital, City-road, E.C.—Clin. Assts.
Royal Northern Hospital.—Asst. Pathologist. £500.
Royal Waterloo Hospital for Children and Women, S.E.—Hon. Asst. Orthopaedic Surgeon.
St. Albans, Hill End Hospital for Mental and Nervous Disorders.—H.P. At rate of £165.
St. Andrew's Hospital, Devons-road, Bow, E.—Asst. M.O. £350.
St. Mary's Hospital, W.—Med. Reg. £200.
Salford Royal Hospital.—Hon. Asst. Physician.
Salisbury General Infirmary.—H.S. At rate of £125.
Sheffield Children's Hospital.—H.P. At rate of £100.
Sheffield University, Dept. of Bacteriology.—Jun. Asst. Bacteriologist and Demonstrator. £300.
Southampton, Isolation Hospital and Sanatorium.—Jun. Res. M.O. £200.
Southend-on-Sea General Hospital.—Obstet.-Reg. £125. Also H.S. At rate of £100.
Stoke-on-Trent, North Staffordshire Royal Infirmary.—Radium Officer. £500.
Taunton and Somerset Hospital.—H.S. At rate of £100.
Tottenham Diagnostic Clinic.—Gynaecologist. £125.
University College Hospital, Gower-street, W.C.—Asst. Radiologist. £200.
University College Hospital Medical School, W.C.—Jun. Fellows for Beit Memorial Fellowships. Each £400.
Uxbridge, Hillingdon County Hospital.—Jun. Res. Asst. M.O. At rate of £250.
Walsall, Manor Hospital.—Jun. Res. Asst. M.O. £150.
West Bromwich and District General Hospital.—Cas. O. At rate of £200.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. and Jun. Res. H.S.'s. At rate of £150 and £100 respectively.
West London Hospital, Hammersmith-road, W.—H.P. and H.S. to Spec. Depts. and Res. Cas. O. Each at rate of £100. Non. Res. Cas. O. £250. Also Physician.
West Sussex County Council, &c.—Asst. County M.O.H., &c. £800.
Wigan, Royal Albert Edward Infirmary and Dispensary.—H.S. At rate of £150.
Willesden General Hospital, Harlesden-road, N.W.—Res. Cas. O. At rate of £100.
York County Hospital.—H.S. to Eye, Ear, Nose, and Throat Dept. £150.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Pontesbury, Salop.

Medical Referee under the Workmen's Compensation Act, 1925, for the Halifax County Court District (Circuit No. 12). Applications should be addressed to the Private Secretary, Home Office, Whitehall, London, S.W.1, before March 28th.

ADDRESSES AND ORIGINAL ARTICLES

MEDICAL PROBLEMS IN MINERAL METABOLISM*

BY R. A. McCANCE, M.D., Ph.D. Camb.,
F.R.C.P. Lond.

ASSISTANT PHYSICIAN IN CHARGE OF BIOCHEMICAL RESEARCH,
KING'S COLLEGE HOSPITAL, LONDON

I.—LEGACIES OF EVOLUTION

"That the physician of another age will be as familiar with the operations of the animal economy as he is at present with its anatomy I have not the least doubt and . . . I will venture to predict that what the knowledge of anatomy at present is to the surgeon, in conducting his operations, so will chemistry be to the physician in directing him generally, what to do and what to shun; and, in short, in enabling him to wield his remedies with a certainty and precision of which in the present state of his knowledge he has not the most distant conception."⁶⁶

THE words are those of William Prout, Goulstonian lecturer in 1831. That prophesy was a bold one to make over one hundred years ago, but I think it has been justified by the events of the last few years. Chemistry is one of the "growing points" of medicine to-day, and I make no apology that my subject is a biochemical one. You have heard from recent Goulstonian lectures something of the metabolism of calcium, phosphorus,⁴⁰ and iron.¹⁰⁷ My theme is also one of mineral metabolism, and while I propose to say something of the above elements in my first lecture, I hope to deal mainly with the importance of sodium in physiology and medicine.

The minerals in the world to-day are those which were there when life began. Their properties have not changed in any way. As life evolved some twenty or thirty of them have been incorporated into living matter, some in very small amounts, and this "mineral basis of life"⁹¹ is one of the most interesting aspects of evolution. Some elements are almost universally present in living matter; others—e.g., vanadium and cadmium—only seem to have been used by one or more families. Sometimes the same element has been used to fill many functions, sometimes the same function has been served by two or more elements. Our own mineral metabolism is the legacy of the ages. We can only appreciate it by a study of the past.

The Mineral Background of Evolution

CALCIUM AND IRON

Puzzling and diverse as some of the functions of the elements seem to be, their chemical properties must govern and have always governed their biological behaviour. Of the six metals (sodium, potassium, calcium, magnesium, iron and copper) commonly present in living matter in considerable quantities, calcium is the one with the greatest tendency to form insoluble salts. The carbonate, phosphate, oxalate and stearate at once come to mind. Now of these the carbonate and phosphate have been very widely used as hardening agents, the former by the invertebrates for their protective exoskeleton, the latter by the vertebrate phylum for their bones and teeth. Birds have utilised both

the phosphate and carbonate. On the other hand calcium is not the only biological metal with insoluble salts. Sodium and potassium form none, but iron possesses an insoluble phosphate and some of the organic phosphate esters have iron salts which are quite insoluble even in hydrochloric acid. Very insoluble forms of ferric oxide are also known. There is therefore no theoretical reason why iron should not have been adopted as the universal hardening agent, although its scarcity is a sufficiently practical one. It has as a matter of fact been so used by some of the marine invertebrates, and this is a beautiful example of Nature's ability to solve a similar problem in two quite different ways. The radular teeth of the Chitonidæ contain ferric oxide embedded in a stroma of unproven nature, and the Patellidæ also possess teeth so impregnated with this same insoluble ferric oxide that beautiful X ray photographs can be taken of them.⁴⁴ These animals are particularly interesting because they illustrate the use of another hardening agent, silica, which has been extensively used by the sponges and other lower forms of marine life, but which has found no place in the structure of the vertebrates. Their central teeth consist of a siliceous framework, packed with ferric oxide, which is so insoluble that it can only be removed by prolonged heating with concentrated hydrochloric acid.

There is some evidence that calcium and iron may be biologically associated—but not of course in all their functions. Iron is a constant impurity in marine shells,^{13 51} and there is evidence that iron may be present in normal and pathological calcification.¹⁰⁸ Ramage et al.^{67 70} have found that in the livers of fetuses and young animals there is a tendency for iron and calcium to rise and fall together. In hæmochromatosis also there may be some associated disturbance of calcium metabolism.^{69 92 93} On the other hand calcium is not apparently necessary for life even in highly developed forms. Lower plants containing no chlorophyll may be successfully grown on calcium-free media, and it has recently been shown that *Drosophila*, a fly, may have 99 per cent. of its calcium removed without loss of function. This interesting work of Rubinstein et al.⁷⁹ on yeast and *Drosophila* show how unwise it is to generalise from the frog or mammal as to the rôle of ions in neuromuscular physiology.

The very property which makes an element so invaluable in one respect may make it a source of difficulty or even danger in another. I need not recall to you the way in which insoluble calcium salts form concretions in the urinary and biliary systems, the salivary ducts and other embarrassing situations. That iron does not do so also is, I think, only due to the fact that so little free iron is present in the body fluids.

There can be no doubt that the development of a satisfactory method of excreting these elements with insoluble salts must have been a *sine qua non* of evolutionary survival. In considering evolution we are inclined to think anatomically. Thus loss of shell is a frequent event in the evolution of some of the invertebrate phyla. We regard it as a commonplace, but just consider for a moment what a strain must have been thrown on the mechanisms for excreting calcium when such an evolutionary step occurred. Many species have managed it successfully, but I feel sure that the calcium metabolism of allied species with and without shells would prove

M

* The Goulstonian Lectures for 1936, delivered before the Royal College of Physicians of London on March 5th, 10th, and 12th. Lects. II. and III. will appear in forthcoming issues of THE LANCET.

an interesting study. I have found, for example, that one of the nudibranchs (*Archidoris britannica*) contains 2 per cent. of calcium. This is not organised into any useful structure but seems to be present throughout the tissues in the form of the carbonate, which forms 20 per cent. of the total dry weight of the animal. I believe that this may well be the result of inefficient excretion coupled with the loss of the power to form a shell. I venture to suggest that man would never have been evolved at all if the early mammals had not acquired the property of excreting almost all their unwanted calcium by the bowel, where the insolubility of its salts could not cause mechanical obstruction.

The insolubility of so many of the calcium salts may be a source of danger for another reason, for it may prevent enough of the food calcium being absorbed to supply the needs of the animal. Excess of inorganic phosphates may do this, especially if the stomach juices are not acid. The masses of fatty acids which pass through the gut in sprue and celiac disease without being absorbed bind calcium as the insoluble soaps⁸⁰ and prevent its absorption. The calcium in spinach is said to be quite unavailable²⁴ because of the excess of oxalic acid present in this plant. I think it quite likely that there may be enough oxalic acid in a helping of rhubarb or strawberries to immobilise all the calcium eaten at that meal.

There is no doubt that the physiological and pathological chemistry of calcium is largely bound up with that of the associated ions. Consider for example the extraordinarily low serum calciums which have been recorded in chronic interstitial nephritis^{81 101} and which are almost certainly secondary to the high levels of inorganic phosphate which are met with in that disease.⁸⁰ Concretions form because free fatty acids, or bile-pigments, or phosphates, accumulate and precipitate themselves out with the calcium which is universally present. I will give you what I consider to be a good example of this. In the rare disease known as calcinosis plaques of calcium phosphate accumulate beneath the skin. They are sometimes surrounded by fluid. I have had the opportunity of examining one of these cases in which fluid was withdrawn on two occasions within a few weeks of each other. The results of the chemical examinations are shown in Table I., and you will

TABLE I
Ca/P. Ratios in Calcinosis Fluid

	First withdrawal.	Second withdrawal.
Calcium ..	580 mg./100 c.cm.	123 mg./100 c.cm.
Phosphorus ..	260 mg./100 c.cm.	227 mg./100 c.cm.
Ca/P. ratio ..	2.22	0.54

see that on the first occasion the calcium and phosphorus were present in large amounts and in the ratio in which they are found in bone, while on the second the fluid was rich in phosphorus but contained relatively little calcium. I conclude that the calcium had not yet had time to accumulate, for I believe from other examinations of internal deposits which I have made that calcium would have been deposited until a calcium/phosphorus ratio approaching that of bone had been achieved.^{102 103}

IRON AND COPPER

We do not know whether iron was a part of the first globule of living matter or not, but we do know that it is one of the most important elements in our own life processes. From the evolutionary and

medical points of view the relationships of iron and copper are most interesting. I need only refer to the fact that the latter is in some way essential for the synthesis of hæmoglobin in the higher animals.³ The two metals have chemical properties in common which have been adopted by Nature for oxygen transport. The two pigments hæmoglobin and hæmocyanin, the respiratory pigment of the arthropods and molluscs,⁴ contain iron and copper respectively. Both form an oxygen, a carbon monoxide and nitric oxide compound with the reduced metal, and an oxygen compound with the metal at its higher valency,⁷¹ so that functionally they are very alike. They seem to differ sharply, however, in the chemical nature of the group with which the metal is combined. In hæmocyanin this appears to be a sulphur compound with a peptide,⁷¹ and the narrow distribution of hæmocyanin may be due to the limitations of these essential prosthetic groups. In hæmoglobin on the contrary the iron is combined with a pyrrole derivative—porpherin—so that the problem of oxygen transport has been solved in two quite different ways, and we have the two metals serving the same function in virtue of the fact that they possess different prosthetic groups.

Now in addition to their share in oxygen transport porphersins seem to be of almost universal distribution, and, whereas iron is the metal commonly attached to them, copper porphersins are also found in nature. The best known of these have no respiratory function and form the colouring matter in the feathers of the South African bird turaco. On the other hand the iron porphersins are the great respiratory catalysts of the organic world, so that here we have the two metals combined with the same prosthetic group and serving different functions.

These iron porphersins seem to be present in every active aerobic animal and vegetable cell.⁴⁵ It is this iron complex in yeast with which cyanide combines.¹¹⁰

Iron is known to have many other functions. Yeast, which can only respire in the presence of organic hæmatin iron, can only ferment in the presence of inorganic, probably ferrous, iron.¹¹⁰ Inorganic iron, and to a less extent hæmatin iron, activate catalysts like glutathione³² and enzymes, and this metal has no doubt many functions of which we have not as yet got any conception. Why, for example, should the epithelial cells of the higher animals double their iron content quite rapidly at the close of the growth period, and thereafter maintain it at the higher level¹⁰⁹? We do know, however, that two forms of iron are present in every cell which depends upon oxygen for its respiration, and therefore that our food contains these two forms of iron. Are both equally valuable? This is a question which has received considerable attention in the last 10 or 15 years.

The Availability of Organic (Hæmatin) Iron in Nutrition

Whipple and Robschelt-Robbins¹⁰⁴ found that hæmoglobin was well utilised by anæmic dogs for blood regeneration when it was administered parenterally, but that only some 5-20 per cent. of it was so used when it was taken by mouth. Lintzel tried the experiment of adding 50 ng. of iron on one day to the diet of a man in iron equilibrium, and found that some 15-18 mg. of the metal were retained when it was given as the sulphate or chloride, but none when it was given as hæmoglobin. These are observations which can be supported on clinical grounds, for all are familiar with the way in which

very small but often recurring hæmorrhages into the gut can bring about a profound anæmia. Lintzel⁴⁹ has maintained rats for 4-6 weeks on an iron-free diet and to this diet added iron in various forms. Ferrous sulphate and the chloride were well retained and stored, but not so hæmoglobin iron. The bodies of the animals which had been given hæmoglobin contained no more iron in their bodies than the controls. Elvehjem, Hart and Sherman²¹ compared the rate of hæmoglobin regeneration caused by various foods with the amount of inorganic iron they contained, and found there was a close parallel. We may conclude therefore that iron in the organic tetrapyrrole form is a poor source of iron for the body, and it is most satisfactory and interesting that copper in this form should also have been shown to be quite unavailable.⁵² I think this unavailability must be due to the fact that mammals have never evolved a digestive ferment capable of setting free iron from these porpherin compounds. Lintzel, for example,⁵⁰ and others have shown that only some 5-10 per cent. of hæmoglobin iron can be set free by prolonged peptic and tryptic digestion *in vitro*, and that some of the iron in plants may also be most resistant to such treatment. Many attempts, mostly biological,^{76 76 77} have been made to determine the available iron in food. These tests are not easy to carry out, and yet it is clearly important to know the proportions of porpherin and ionisable iron in our daily diets.

L. R. B. Shackleton and I⁵³ have accordingly made a chemical survey of all the common foodstuffs eaten in this country and a synopsis of the results is given in Table II.

TABLE II
Available Iron in Foods

Expressed as a percentage of the total iron			
Beef muscle ..	8-28	Cereals ..	80-100
liver ..	80-100	Cabbage, lettuce, &c. ..	50-75
Chicken muscle ..	25-35	Legumes ..	70-95
Fish (white) ..	95-100	Tomatoes ..	50-80
„ (herring) ..	55-75	Plums ..	50-70
Eggs, hen ..	100	Apples and pears ..	80-100
Roe, herring ..	98	Grapes, raisins, &c. ..	86-96
		Nuts ..	60-95

You will notice that little of the iron in meat but nearly all the iron in liver, eggs, white fish and cereals is available. Most vegetables and many fruits fall into an intermediate category, but some fruits and nuts contain a very high percentage of their iron in available form. It follows at once from these figures that meat, for all the iron it contains, may be a poor source of the metal, and foods like eggs and brown bread are really as good although they do not contain so much total iron. Miss Widdowson and I have found that a person on a mixed diet, but eating over half a pound of meat per day, was taking in 22.1 mg. of iron per day of which only 9.3 mg. were available. A second person, who ate practically no meat, was only taking in 9.3 mg. of iron per day from the food, but 8.6 mg. of it was available. I think that in future we shall probably assess iron requirements on the basis of available rather than total iron.

Total and Available Iron in English Diets

I think I am right in saying that all surveys of British diets have been made by the "family" method, and that there are no records of the weighed food intakes of individual normal men and women. We know that the calorie requirements of women are very much less than those of men, but that the needs of the two sexes, expressed as calories per kilogramme of body-weight are more nearly the same. We

have no right to assume that these relative requirements of the two sexes apply to iron and other inorganic salts. We have every reason in fact to suppose that they do not. One has only to consider the drain of menstruation, pregnancy and lactation on women's stores of iron and calcium to realise that their needs for these minerals must be greater than men's.

Miss Widdowson and I¹⁰⁶ have carried out a survey by the individual method. We persuaded 63 men and 63 women of the middle classes to weigh all their food for a week, and from this data and our own food analyses we have worked out each individual's protein, fat, carbohydrate, calcium, iron and phosphorus intakes. We are only concerned for the moment with their iron intakes, which are summarised in Table III. Considering the total iron

TABLE III

Iron Intakes and Hæmoglobin Levels of Middle-class Men and Women

	MEN			WOMEN		
	Mean	Max.	Min.	Mean	Max.	Min.
Total iron mg./day ..	16.8	28.5	7.8	11.4	17.3	5.5
Total iron mg./kg. body-weight/day ..	0.24	0.18
Available iron mg./day ..	10.8	18.7	5.3	7.9	12.4	5.0
Available iron mg./kg. body-weight/day ..	0.16	0.13
Hæmoglobin percentage .	102	114	86	93	102	87

first you will observe that the average woman's intake was far below the man's, and the highest woman's figure only just exceeded the man's average. If you look at the intakes per kg. of body-weight you will see that even on this basis the women's intakes are well below the men's. This difference between the sexes is partly due to the higher consumption of meat by the men. The intakes of available iron per kg. of body-weight are more nearly the same, but there is still a balance in favour of the men which is simply explained by the greater amount of food eaten by them. This difference would not matter if all intakes were well up to or over the optimum, but this is not likely to be generally the case for many of these individual intakes are lower than the accepted American and English standards. At the same time there can be no serious iron deficiency among these people, for their average hæmoglobin levels were normal and the male/female ratio also normal.

When we began, however, to think over the so-called normal difference between the hæmoglobin levels of the sexes and to consider it in the light of their iron intakes and iron requirements, we could not help feeling that the difference might not be physiological after all, but pathological. We therefore administered 100 mg. of iron per day to a group of 31 normal men and women, mostly between 20 and 30 years of age. This treatment did not alter the hæmoglobin level in the men's blood but raised it without exception in the women's. The average increase was over 10 per cent., and the result of treatment was to leave the two sexes with almost the same average percentages of hæmoglobin. I think we must conclude that the hæmoglobin levels of normal women in this country are being limited by their low iron intakes. They would probably be better and fitter on larger intakes and this could, I think, be settled if a sufficiently comprehensive investigation was

undertaken. It would appear that men get enough iron for their physiological requirements in this country, but I think it possible that their rate of acclimatisation to high altitudes, which depends partly upon new hæmoglobin formation, may be controlled by their iron intakes.¹⁰⁶

Phosphorus

I turn now to another element, phosphorus, which I believe is essential to all living matter. It is the shortage of this element in sea water which limits the development of the plankton, upon which practically all animal life in the sea depends. I only propose to touch upon one very small aspect of phosphorus metabolism, and my real excuse for doing so is that it has been occupying my attention for the last 18 months.

In the course of their evolution the seed plants have developed the property of forming and storing large amounts of a substance called phytin. This is the calcium magnesium salt of inositol hexa-phosphoric acid. Inositol has the empirical formula $C_6H_{12}O_6$, and resembles the carbohydrates in having 6 -OH groups and a sweet taste, but differs from them in most other properties, particularly in possessing a cyclic structure. I suppose it is true to say that the efficiency of seeds depends to a large extent upon the fact that they contain the maximum amount of nourishment for the embryo combined with the minimum amount of moisture, and from this point of view phytin must be regarded as an almost ideal product, for it offers a means of storing carbon, hydrogen, phosphorus, calcium and magnesium in an inert and quite insoluble form.

In that the seeds of plants may form a very important part of man's diet, we have to consider the question of phytin in human nutrition. Many have assumed that the phosphorus calcium and magnesium are freely available, but there is plenty of evidence which suggests that they may not be. In the first place mammals have never evolved an intestinal enzyme capable of hydrolysing phytin and setting the phosphorus free in inorganic form,⁶³ and phytin itself is most unlikely to be absorbed without being hydrolysed. It is indeed easy to show that 25 to 65 per cent. of ingested phytin is excreted unchanged. I myself ate a pound of Hovis bread every day for 10 days which meant that I was having about 430 mg. of phytin phosphorus per day (in addition to all the other wonderful things in brown bread!). I excreted just under 50 per cent. of this phytin phosphorus unchanged in my faeces and the remainder was probably destroyed by the bacteria in my large intestine.⁵⁴ We must conclude that phytin phosphorus is largely unavailable. In the second place, if phytin is not digested it may hold large amounts of calcium in the gut as the insoluble salt and so prevent the latter's absorption. In this way phytin, by being itself unavailable, may render calcium unavailable also.

It has often been claimed that cereals tend to promote rickets. Bruce and Callow⁹ suggested that this might be due to the phytin in the cereals. The whole question is a very open one at present,^{25 31 48} but it seemed to me that we ought to know how much phytin there was in human food, so Miss Widdowson devised a method of estimating it and Table IV. shows some of our results. You will see what a high percentage of the phosphorus in whole wheat and oats is in the form of phytin. White bread contains much less phytin, but also much less total phosphorus. Nuts contain large amounts of phytin

TABLE IV

Total and Phytin Phosphorus in Foods

Edible portions only have been analysed. Results are expressed on the basis of fresh or purchased weight.

	Total P.	Phytin P.	
	Mg./100 g.	Mg./100 g.	Per cent. of total P.
Cereals—			
Wholemeal flour ..	355	168	46

Figs (dried) ..	91	12	13

phosphorus, but vegetables and fruits little or none. By applying these results to the dietary survey, to which I have already referred, we were able to find out how much total and phytin phosphorus people in this country were eating. The results are in Table V.

TABLE V

Total and Phytin P. Intake of Men and Women

	Men. (Mean of 63)	Women. (Mean of 63)
Total P. (g./day)	1.61	1.13
Phytin P. (g./day)	0.04	0.04
Non-phytin—i.e., available P. (g./day)	1.57	1.09
Available P. as percentage of total P.	98	97

You will see that in English diets phytin phosphorus forms a very small percentage of the total phosphorus. There are two reasons for this. Firstly, we derive a very large part of our phosphorus from meat, milk and other animal products which contain no phytin. Secondly, the majority in this country do not eat whole cereals but white bread, and, as you see in Table IV., this contains very little phytin. I think that in English diets phytin may almost be neglected. There is plenty of phosphorus in the food without it, and not enough of it to be a real danger to calcium absorption. It may be quite otherwise with native diets in which maize, millet, &c., form the bulk of the food. In them half the total phosphorus ingested may be unavailable, and possibly the calcium as well.

The Alkali Metals, Sodium and Potassium

I wish now to turn to other aspects of mineral metabolism and say something of the importance of sodium and potassium. All the common salts of these metals are freely soluble. While this normally ensures complete absorption from the intestine it carries with it certain disadvantages, for there is no way in which the body can store reserves of these elements in an insoluble and inactive form. Although so much alike chemically and physically sodium and potassium fulfil quite different biological rôles, for animals and plants have universally adopted potassium as the main cellular base and sodium as the

extracellular ion. The cell membranes once formed seem to be almost impermeable to these soluble kations, so that cells bathed in a medium rich in sodium may contain none of this element. It has been shown experimentally that one of the marine diatoms, and possibly some of the seed plants, can substitute rubidium for potassium in cellular growth,⁹⁹ so that potassium may not be essential for life in its general sense. Higher animals must have potassium, although rubidium is an element commonly found in traces in living cells.⁹⁴ Zwaardemaker¹¹¹ showed that uranium could replace potassium in fluids used to maintain the frog's heart beat. I do not think that the possibilities of potassium substitution in animals or plants have been fully explored.

Since sodium has been adopted as the main extracellular base, vertebrates and invertebrates with elaborate extracellular circulatory systems must contain considerable amounts of this element, and obtain it from their food. With no reserves to draw upon a constant supply is important, and although periods of deficiency can be survived if excretion can be cut down to a minimum, the moment the rate of excretion is forced up large amounts must be supplied or the most serious consequences will ensue. Plants, which have no such extracellular systems, may contain practically no sodium. Some insects also⁷⁹ appear to be able to thrive on minimal amounts of this element. *Drosophila* for example can flourish when 95 per cent. of the sodium in its body has been removed, and possibly may be able to do without any at all. The discovery that such a highly organised creature as *drosophila* can do without sodium is an extraordinarily interesting one. It is fully as significant theoretically, although not perhaps so important economically, as for example the discovery that sheep require cobalt.⁶³

been developed in recent years for studying it. These consist essentially in methods of differentiating the function of the glomeruli and tubules. There have been several interesting developments. It has been found possible in frogs and snakes to insert a cannula into a single intact glomerulus and withdraw the glomerular fluid for analysis. In this way it has been shown that in the frog, *necturus*, and snake^{59 74} the fluid filtered off in the glomeruli resembles plasma closely in composition except that it contains no protein. It does contain sugar, urea, chlorides and phosphates in the concentration in which they occur in plasma. Since the normal urine of these animals contains no sugar, reabsorption of this substance and water must take place in the tubules. Owing to the double blood-supply of the frog's kidney it is also possible to perfuse the tubules through the renal portal vein without perfusing the glomeruli. In this way it has been shown that the tubules of the frog's kidney do not excrete soluble sugars such as xylose, which readily pass into the urine of the intact animal.⁸⁸ The inference is that these sugars are filtered off in the glomeruli of the intact animal. This conception of the function of the tubules and glomeruli is very much supported by the study of the secretion of urine in glomerular and aglomerular fish.^{56 57 58} The glomerular fish excrete xylose readily and other soluble foreign substances such as thio-urea and inulin. Glucose appears in their urine if they are given phloridzin. The aglomerular fish do not excrete xylose, sucrose or inulin⁹⁰ and do not get glycosuria after phloridzin. This evidence all strongly suggests that the function of the glomeruli is to filter off all the soluble constituents of plasma, and that water and some soluble substances—e.g., glucose—are reabsorbed by the tubules. The aglomerular fish, however, can excrete creatinine, so that the tubules of these animals have also an excretory function.

If we knew of some substance which was freely filtered off in the glomeruli so that its concentration in the glomerular fluid was equal to that of the plasma, and if we knew that this substance was not reabsorbed or excreted by the tubules, we could use it as a measure of glomerular filtration. Then, by comparing its rate of excretion with that of other substances, we could find out how the latter were being dealt with by the kidney. This method is applicable to mammals and man, and much of the work of the last ten years on the secretion of urine has been devoted to the search for such a substance. Rehberg, I think, first suggested that creatinine might be used for this purpose in man. He took creatinine by mouth to raise the plasma concentration and estimated the plasma and urine concentrations and the volume of urine secreted in unit time. Now the volume of fluid filtered off in the glomeruli per minute

$$= \frac{\text{percentage of creatinine in urine}}{\text{percentage of creatinine in blood}} \times \text{vol. of urine per min.}$$

You will at once recognise that this formula is the same as that giving what is otherwise termed the creatinine clearance. Creatinine has been accepted by a number of continental workers, often without question, as a true measure of glomerular filtration.^{5 6 7 8 11 19 22 23 27 30 39 41 47 64 65 108}

Some have produced experimental evidence in its favour in the following way. Phloridzin has been known for a long time to lead to glycosuria, and, taking all the evidence together, phloridzin may be assumed to abolish the reabsorption of glucose in

TABLE VI

Sodium Content of Some Common Foods

	Mg./100 g.		Mg./100 g.
Meat	65-80	Cereals	5-30
Milk	43	Potatoes	3-4
Eggs	185	Vegetables—	
Organs—		Green	3-15
Liver, brain, kid-		Root	10-60
ney, &c. ..	110-160	Fruit	0-3
Fish	120-190	Nuts	2-10

Average human intake/day: 3000-6000 mg.

Table VI. shows the amount of sodium in a number of common food materials. You will notice how little some of them contain, and appreciate that additional salt may be an absolute necessity when I tell you that I would have to eat more than twice my own weight of potatoes every day to get my physiological intake of sodium. Men were mining for salt 4500 years ago at Igidir.⁸⁰ It is in hot climates where sweating is more or less continuous that salt becomes such a very important article of diet. A man may lose 3000-4000 mg. of sodium in a day by sweating, and a study of Table VI. will show that cereals without added salt would be a most inadequate diet.⁵²

Water Regulation

THE FUNCTION OF THE GLOMERULI AND TUBULES

The water regulation of the body is undoubtedly one of the key problems of comparative physiology, and it is intimately linked with the metabolism of sodium and potassium and the evolution and function of the kidney.

I cannot discuss water regulation or the metabolism of sodium without some reference to the function of the kidney, and the methods which have

the tubules. Govaerts and Cambier^{28 29} and Poulsson⁶⁴ therefore compared the clearances of glucose and creatinine in fully phloridzinised animals and found them to be the same. These experiments were done on dogs, and the results were assumed to apply to man. More recent work has shown that this is probably not the case (*vide infra*).

Nevertheless there is a great deal to be said against the indiscriminate use of creatinine as a measure of glomerular filtration.¹⁸ In the first place it is excreted by the aglomerular fish, so that somewhere in the scale of evolution creatinine was actively excreted by the tubules. In the second place the rate of excretion of creatinine may be,¹⁵ but apparently is not invariably, directly proportional to the plasma concentration, which is a *sine qua non* of any substance used to measure glomerular filtration.^{35 84 85 86}

In connexion with some work on the absorption of sugars from the intestine, McCance and Madders⁵³ suggested in 1930 that the pentose sugars might be used as measures of glomerular filtration. These non-metabolised sugars were later independently suggested and investigated in the United States. At first the American investigators accepted these sugars as true measures of glomerular filtration.^{12 14 42 43 62 88 89} They found, as has Cope,¹⁶ that their clearances were below that of creatinine, and they therefore considered that the latter was to some extent excreted by the tubules. They also found that after phloridzin the clearances of glucose and the non-metabolised sugars were the same. Höber, however, reported that xylose was reabsorbed to a small extent by the frog's tubules, and if this is true of other animals these sugars cannot give a true measure of glomerular filtration.

The latest compound to be used to measure glomerular filtration rate is inulin. This is a polysaccharide with a molecular weight of 1000-4000, and therefore most unlikely to diffuse readily out of the tubules or to be reabsorbed. It is freely soluble in water and filtered off in the glomeruli. This substance has been used by Shannon and his collaborators,^{84 86 90} who now admit that the pentose sugars and cane sugar are all reabsorbed to some extent and do not give an absolute measure of glomerular filtration. Inulin apparently is perfectly satisfactory. Glucose and other sugars may only be used if reabsorption has been blocked by phloridzin. Creatinine may be used in the dog^{73 86 87 105} but not in the fish, in which it is actively excreted by the tubules, nor in man, in whose tubules some active excretion also appears to take place.⁸⁵

All methods of measuring glomerular filtration suggest that large amounts of fluid must be filtered off there—between 100 and 150 c.cm./min. in a normal man. Since the normal rate of urine secretion is only about 1 c.cm./min., 99 per cent. of the water in the glomerular filtrates must be reabsorbed.

THE WATER REGULATION OF MARINE ANIMALS

As already stated, cell membranes, except those of the glomeruli and capillaries, are not ordinarily permeable to cations. They are, however, freely permeable to water so that cells are subject to the laws of osmotic pressure. These statements are as true of the complicated multicellular organism as they are of its individual constituent cells. We know, for example, that fish have a more or less constant mineral composition, and yet experiments with heavy water have shown that equilibrium between the water inside and outside of a small

living fish is attained in an hour.³⁶ Now all vertebrates at the present time have an osmotic pressure very much greater than that of fresh water, but very much less than that of the sea. It is now thought that they were evolved in fresh water.^{95 96} However that may be, all the water swallowed by a fish living in fresh water tends to dilute the plasma, and water must also be absorbed through the gills. Their glomerulo-tubular kidneys deal effectively with this. The high rate of glomerular filtration offers a ready means of separating water from the blood. The tubules reabsorb glucose, the necessary salts, and some water. The excess, which is excreted, results in the passage of a very dilute (hypotonic) urine. As the seas became more salt or as the free swimming vertebrates made their way into more saline waters, the whole situation changed. The environment became more concentrated than the tissue fluids. Thus instead of water passing into the fish there was a tendency for the water to pass outward through the gills, and for the animal to become desiccated. This could have been corrected by the production of a sufficiently concentrated urine, but the marine fish have never evolved the power to secrete a urine more concentrated than their plasma, and solved the problem of their water regulation in other ways^{95 96} (see later). Mammals can secrete a hypertonic urine, and this ability seems to be associated with the introduction of the so-called loop of Henle into their kidneys and the elaboration of a hormone in their posterior pituitary.¹⁰ Different species of mammals possess the power to secrete a hypertonic urine to very different degrees. Thus man can undoubtedly produce a urine much more concentrated than his plasma but not sufficiently concentrated to allow him to use sea water as his natural beverage.

"Water, water, everywhere
No any drop to drink."

We may say I think with confidence that if mermaids really did live in the sea they certainly did not have a pair of human kidneys. There are nevertheless marine mammals, and they must drink sea water and yet retain control of their water metabolism. I am not aware of any study having been made of the kidney function of these animals, but I imagine it would be relatively easy and be well repaid.

The marine fish, which you will remember live in a hypertonic medium but are unable to secrete a urine more concentrated than their blood, have solved the problem of their water regulation in two quite different ways.^{95 96} The bony fish drink sea water, which is absorbed, and excrete through their gills⁴⁶ a solution of sodium chloride more concentrated even than the sea. The result of this is to leave enough free water in the tissue fluids to enable the animal to elaborate the hypotonic and almost chloride-free⁶¹ urine. Owing to the extrarenal excretion of salt and water the secretion of water by the kidneys of the marine teleosts is very small. Glomerular filtration is really unnecessary, and hence some of the more highly developed forms have lost all their glomeruli. The elasmobranchs, on the other hand, have perfected quite another mechanism, and it is to this which I wish particularly to draw your attention. These animals have gills which are impermeable to urea. Their glomerular function is quite normal. Soluble salts are readily excreted, and also xylose and inulin, which are not excreted by the aglomerular fish, but the urine contains only traces of urea in spite of concentrations of 1 per cent. and more in the plasma.

It has been shown¹⁴ that this is due to the active reabsorption of urea by the tubule cells so that ultimately the animal becomes hypertonic to sea water by virtue of the urea which it contains. Water therefore is absorbed from the sea by osmosis through the gills and possibly other parts, and this enables a hypotonic urine to be secreted. Here then we have an example of the active reabsorption of an end-product of nitrogen metabolism, and interest lies in the process because it can be shown by any of the methods of measuring glomerular filtration that something of the same sort goes on in many other animals, including man. It may seem strange to you, but I think we must accept it, that a large part of the urea filtered off in our glomeruli either diffuses back into the blood stream or is more probably actively reabsorbed. I shall have more to say on this subject in a subsequent lecture.

WATER REGULATION IN MAN

Clothes moths and snakes can exist for long periods of time on their own water of metabolism,⁷⁸ but most animals and man must have a regular supply of water. In its absence urea accumulates in the blood but the nitrogen balances become negative so that a generalised tissue disintegration must set in. Death soon follows. The urine volumes are well maintained until the end, partly no doubt by the water set free from the cell breakdown, but the cause is not at all clear.^{55 98}

Too much water is just as fatal as too little.⁹⁷ Animals may readily be killed by pushing the administration of water. At first a diuresis develops, but later and most unexpectedly the animals get an oliguria, and finally an anuria. Towards the end they get convulsions from cerebral oedema.¹⁷ Patients have been killed in the same way.³⁴

Everyone recognises that if water is taken by mouth the usual consequence is the passage of additional dilute urine and the restoration of the *status quo*.¹ This apparently simple function is in reality a complicated one.^{2 60 100} The water absorbed lowers the osmotic pressure of the plasma, but the diuresis does not coincide in point of time³ so that one cannot postulate a simple renal mechanism regulating the osmotic pressure of the plasma. Moreover, if the plasma osmotic pressure be reduced in other ways, no diuresis is produced, and water then brings about less diuresis than before.³

The regulation of water metabolism in man is a difficult study because of many,⁶⁰ but in particular I think because of two, complicating factors. In the first place the excretion of water has in the course of evolution come under the control of a hormone from the posterior pituitary,¹⁰ and the simple and well-known relationship between drinking and diuresis only holds so long as the supply of hormone to the circulation is normal.¹⁰⁰ In the second place, owing to the constancy with which mammals maintain their osmotic pressure, water metabolism and salt metabolism are intimately connected. Movement of water about the body is almost invariably accompanied by simultaneous movement of salts. The converse is also true. Thus the excretion of sodium salts brings about a reduction of the extracellular fluid volume, and a loss or gain of cell substance a corresponding change in potassium.²⁶ One of the most interesting recent developments in mineral metabolism is the discovery that the renal threshold for sodium seems to be controlled by the suprarenal cortex. At all events, in its absence and in Addison's disease forced excretion of sodium takes place with consequent changes in the water

balance of the body. I hope to discuss this more fully in my later lectures.

Let me close meantime by drawing your attention to an aspect of mineral metabolism and comparative physiology which I am sure will repay investigation. I refer to the control of so many aspects of mineral metabolism by the ductless glands, or by vitamins. The parathyroids, the thyroid, the suprarenal cortex, the posterior pituitary and vitamin D are all directly concerned with the water or mineral metabolism of the higher animals. Some would include vitamin A, but I prefer to regard the concretions produced by its absence³⁷ as being secondary to the changes in the urinary epithelium or pH.

When were these factors controlling calcium, phosphorus, water and sodium metabolism evolved? And what of potassium, magnesium, and iron? So far no controlling hormone for these elements has been discovered, but this is no proof that such a hormone does not exist.

NEW HOSPITAL IN PONTEFRACCT.—By the will of Mr. W. H. Hydes either a maternity or a children's hospital is to be erected in the poor part of Pontefract. It is to be known as the Hydes Hospital and will be administered by the governing body of the General Infirmary. The sum bequeathed by Mr. Hydes is said to be about £65,000.

THE VIRUS ÆTIOLOGY OF ONE FORM OF LYMPHOCYTTIC MENINGITIS

By G. M. FINDLAY, C.B.E., M.D., D.Sc. Edin.

OF THE WELLCOME BUREAU OF SCIENTIFIC RESEARCH

N. S. ALCOCK, M.B. Edin.

RESIDENT MEDICAL OFFICER, THE NATIONAL HOSPITAL, QUEEN-SQUARE; AND

RUBY O. STERN, M.D. Lond.

PATHOLOGIST TO ST. ANDREW'S HOSPITAL, NORTHAMPTON

FROM time to time cases of meningitis of unknown ætiology have been described under a variety of names as serous meningitis, acute aseptic meningitis, or acute benign lymphocytic meningitis. The essential characteristics of the disease, first clearly described by Wallgren (1925), have been recognised in this country, on the continent of Europe, and in America; despite the view of workers such as Eckstein, Hottinger, and Schleussing (1932) who believe that lymphocytic choriomeningitis is an abortive form of either poliomyelitis or epidemic encephalitis there is general agreement that it is undoubtedly a disease sui generis.

Evidence as to the cause of the disease was first obtained by Armstrong and Lillie (1934) in America when, during the transmission in monkeys of infectious material from an individual who had died at St. Louis during the 1933 epidemic of encephalitis, they encountered a previously unidentified virus which in rhesus monkeys caused round-celled infiltration of the meninges and choroid plexus. The pathological condition was, therefore, designated lymphocytic choriomeningitis, the virus being quite distinct from that isolated by Muckenfuss, Armstrong, and McCordock (1933) and Webster and Fite (1933) and shown to be the undoubted cause of St. Louis encephalitis. Later Armstrong and Wooley (1935) isolated two other strains of a virus, pathologically, immunologically, and clinically identical with the first: one of these strains was obtained from a female who died in Maine, the other from a monkey that died after inoculation with the virus of poliomyelitis (monkey strain). These three strains were found to be pathogenic not only for rhesus monkeys but also for mice, though not infrequently individual mice were found to resist inoculation. In those mice that succumbed to the infection there was found, as in monkeys, infiltration of the meninges and choroid plexus with lymphocytes. Armstrong and Wooley (1935) and Armstrong and Dickens (1935) also showed that the sera of persons who had suffered from "aseptic meningitis" in districts as far apart as California, Maryland, District of Columbia, Illinois, Ohio, and Virginia contained immune bodies to the virus of lymphocytic choriomeningitis. At the same time Rivers and Scott (1935) isolated an identical virus from the cerebro-spinal fluid of two laboratory workers, while Traub (1935) isolated the same virus from a strain of apparently normal mice used in laboratory work at Princeton, New Jersey.

There is thus evidence that the virus of lymphocytic choriomeningitis is widely distributed in the United States of America.

The probability that the same or a very closely allied virus was present in this country first arose in the autumn of 1934 when, through the kindness of Dr. J. A. Murray, F.R.S., at the time director of the Imperial Cancer Research Laboratories, one of us (G. M. F.) received a mouse that had exhibited

nervous phenomena. This mouse, which had been the bearer of an engrafted tumour, had been exposed to radium. It was thought that either the radium, by damaging the central nervous system, was itself responsible for the symptoms, or as the result of a local injury some infectious agent had gained access to the brain. The latter view proved to be correct, for mice inoculated intracerebrally with brain emulsion from the first mouse died in 6-8 days with definite nervous symptoms. Cultures made from the brains of these mice were bacteriologically sterile, but filtrates obtained after passage through Berkefeld V candles proved to be pathogenic for mice. Seven passages were made in mouse brains with this virus (M strain) which was found to be pathogenic not only for mice but for rhesus monkeys, rats, and guinea-pigs. It thus seemed probable that the virus isolated by Armstrong and Lillie (1934) was also present in this country. In order that this point might be investigated, Dr. Charles Armstrong of the United States Public Health Service, to whom our thanks are due, very kindly supplied us with a strain of his virus.

Before further investigations were made, however, it appeared to be essential to make certain that the virus was not already present in a latent form either in mice or monkeys in use in the laboratory. With this end in view, the sera of 22 rhesus monkeys were tested for immune bodies to the Armstrong strain of lymphocytic choriomeningitis virus [the A strain]. In none were immune bodies found.

ISOLATION OF LYMPHOCYTIC CHORIOMENINGITIS VIRUS FROM MICE

Three strains of laboratory mice were tested for their reaction to the A strain of the virus. Twelve mice were selected from each strain. Six of these mice were inoculated intracerebrally with 0.03 c.cm. of a 2 per cent. suspension of starch in physiological saline, the other six were inoculated intracerebrally with 0.03 c.cm. of a 10 per cent. suspension in saline of mouse brain infected with the A strain. All three strains of laboratory mice were found to be free from infection, for of the mice infected with the A strain all died with typical symptoms, while all those inoculated with starch remained in good health for the four weeks during which they were kept under observation.

At the same time it appeared to be of interest to determine whether other breeders' mice were infected with lymphocytic choriomeningitis virus. Mice from fifteen breeders were therefore tested as before. All proved non-resistant except one strain. Here, of 12 mice inoculated intracerebrally with the A strain of the virus 5 were completely resistant, while of 12 injected intracerebrally with starch 4 developed symptoms in 6-11 days. Brain emulsions from these mice were inoculated intracerebrally into fresh mice which all died in 6-8 days. Eleven passages have been made with this virus of mouse origin (N strain).

The symptoms produced in mice by the A, M, and N strains are identical. The mice after intracerebral inoculation with a 20 per cent. suspension in saline of infected brain invariably die in 6-8 days. Shortly before death they develop a staring coat and tend to sit quietly in a corner of their cage; sometimes a slight tremor develops; if touched or stimulated in any way at this period they exhibit a form of convulsion, becoming quite rigid with the hind legs extended; in a few seconds breathing stops and the mice are dead, though the limbs still remain stiffly extended after death.

When inoculated intracerebrally the minimum lethal dose is usually 0.03 c.cm. of a mouse brain suspension diluted 10^{-5} or 10^{-6} . At death virus is present not only in the brain but in the blood, kidneys, liver, spleen, adrenal, and lungs. It is also present in the urine, as noted by Traub (1935). When the virus is inoculated intraperitoneally the mice as a rule show no symptoms, though occasionally after a large injection—0.3 c.cm. of a 20 per cent. suspension of mouse brain—death has occurred with the usual cerebral symptoms. After intraperitoneal inoculation virus has been recovered from the spleen and occasionally from the kidney 2½ months later. Virus applied to the lightly scarified skin of the mouse's abdomen may later be obtained from the kidneys and spleen. Virus was also obtained from the same organs of 2 out of 10 mice that had been fed on infected mouse brain ten days previously. Although virus may have been absorbed through the lining of the alimentary canal the possibility in these cases of entry through small wounds on the limbs or about the mouth cannot be excluded. Instillation of the virus into the nostrils of mice under light ether anaesthesia is followed by the development of cerebral symptoms and death.

Mice dying from the disease rarely show any naked-eye pathological lesions. On a few occasions bronchopneumonic patches were present in the lungs; more commonly the liver was pale yellow and fatty or old rose instead of purplish-red in colour.

ISOLATION OF VIRUS FROM HUMAN CASES OF LYMPHOCYTIC MENINGITIS

Preliminary experiment having shown that the stock animals to be used in the investigations were free from infection with the virus of lymphocytic choriomeningitis, an attempt was made to isolate the virus from the cerebro-spinal fluid of patients suffering from meningitis of unknown aetiology. Up to the present it has been possible to isolate the virus from two individuals A. W. and B. C. The clinical histories of these patients are as follows.

THE CASE OF A. W.

This patient, a man aged 46, was admitted to the National Hospital on Oct. 17th, 1935, under the care of Dr. J. Purdon Martin. His family history was negative, and there was nothing of note in his personal history except that some days before the onset of his illness he had cleared out a shed which was heavily overrun with mice.

About five weeks before admission he developed a headache, pain in the back, and a temperature of 102° F., which he attributed to "influenza." These symptoms persisted, and as no cause could be found for the pyrexia he was admitted to the North Western Fever Hospital as a typhoid suspect. No evidence of enteric fever was obtained however during the nineteen days he remained in this hospital. Whilst there he ran an intermittent temperature which rose nightly to 101° F., though it gradually settled towards the end of his stay. On Oct. 5th he became rather confused and slightly hallucinated, and a day or two later pain and tenderness developed over the legs and lower abdomen. On Oct. 11th he found difficulty in drawing up the left leg, and on the following day both legs became completely paralysed. At this time he lost all sensation in his bladder.

Clinical and laboratory findings.—When admitted to the National Hospital on Oct. 17th the patient was obviously confused, though correctly orientated, could not give a connected history, and occasionally used wrong words. The cranial nerves were normal apart from early bilateral papilloedema. The movements of the arms were normal. He was not able to sit up and the only movements possible in the legs were contraction of the right

quadriceps and weak movements of the right ankle and toes. Reflexes: arms-jerks, + a - ; knee- and ankle-jerks, + a - ; abdominal reflexes absent; plantars extensor. Sensation: from the umbilicus down to the level of the fourth lumbar segment there was a marked hyperalgesia with overreaction. Below this level all forms of sensation were impaired. The calf muscles were very tender to pressure. There was complete retention of urine.

The cerebro-spinal fluid, examined on Oct. 18th, was clear and colourless; the pressure was 195 mm. Cells: 138 per c.mm., 98 per cent. lymphocytes, 2 per cent. large mononuclears. Protein: 0.28 per cent. Nonne-Apelt and Pandy reactions positive +. Lange 0112232222. Wassermann reaction negative in blood and cerebro-spinal fluid. The changes in the C.S.F. are set out in the accompanying Table.

Table showing Changes in C.S.F.

	Oct.						Nov.	
	18th	19th	21st	23rd	25th	31st	7th	16th
Pressure (mm.)	195	120	—	—	—	—	—	—
Cells (per c.mm.)	138	182	330	272	168	34	30	9
Lymphocytes (per cent.)	98	100	97	96	—	100	100	100
Large mononuclears (per cent.)	2	0	—	0	—	0	0	0
Polymorphs. (per cent.)	0	0	—	4	—	0	0	0
Protein (per cent.)	0.28	0.15	0.15	0.12	0.09	0.14	0.08	0.10

A blood count on Nov. 27th showed 37,200 white blood-cells per c.mm. (polymorphonuclears, 76.5 per cent.; lymphocytes, 23.5 per cent.).

Progress.—Power gradually returned to the legs and he can now just lift his right ankle off the bed but cannot move the left leg. Tone has increased and ankle-clonus can be elicited on both sides. The plantar responses are extensor. He is unable to sit up without support and he cannot stand. Sensation: the overreaction gradually passed off and by Nov. 26th had disappeared. The analgesia grew steadily less and the only abnormality of sensation now present is some loss of deep sensibility and of bladder sensation. He began to pass urine naturally on Nov. 22nd.*

CASE OF B. C.

Aged 36, this patient was admitted to the National Hospital on Nov. 6th, 1935, under the care of Dr. Gordon Holmes. His personal history and his family history were negative.

Twenty days before admission he developed a slight cold in the head accompanied by sneezing and malaise. Two days later his voice almost disappeared and he had two or three rigors. The following day he felt better and he remained well for four days. On Oct. 24th he felt ill again and complained of an aching pain in the back and insomnia. This pain gradually became more severe and spread up to between the shoulder-blades. A week before admission it decreased in severity but he noticed a tingling in his finger-tips and weakness in his grip. He also found he could not taste normally and his teeth "felt too big." In addition he had slight difficulty in passing urine. By the next day numbness and tingling of the feet developed and his legs became weak. This weakness increased rapidly until he was unable to walk without support. The day before admission there was weakness of the facial muscles on the right side and momentary diplopia occurred.

On admission his temperature was 100° F. He complained of retention of urine. Cranial nerves: There was a slight ptosis on the left side and a facial palsy of lower motor neurone type on the right side. Otherwise the cranial nerves were normal. The movements of both arms were weak, especially at the shoulders. He was unable to sit up in bed. The movements of both legs were so weak that he was unable to stand. Reflexes: All

* Since this was written progress has continued and he is now able to walk.

tendon-jerks were absent. Abdominal reflexes, upper present, lower only faintly present. Plantar responses, both extensor. Sensation: There was a loss of all forms of sensation peripherally in the arms; some impairment below the level of the third dorsal segment, but greater peripherally in the legs. The soles of the feet were tender. Cerebro-spinal fluid (Nov. 6th): pressure, 140 mm.; slightly yellow; fine coagulum formed on standing. Cells: 63 per c.mm., 12 per cent. large mononuclears. Protein: 0.275 per cent. Nonne-Apelt positive +; Pandy positive ++. Lange 0000111122. Wassermann reaction negative in C.S.F. and blood. Blood count (Nov. 6th): white blood-cells, 8200 per c.mm. Nov. 27th: white blood-cells, 11,400 per c.mm. (polymorphonuclears 71 per cent., lymphocytes 29 per cent.).

Progress.—Catheterisation was necessary for three or four days. On Nov. 11th he developed a complete left facial paralysis. Motor power gradually returned and by the 29th he was able to walk, the arms being then almost normal, though the right facial palsy was still present. Sensation had also returned by this time, though the tendon-jerks were still absent and the plantar responses remained extensor. On discharge he had regained practically full use of his limbs, but still had an almost complete paralysis of his right facial muscles, which gave a complete reaction of degeneration.

Cerebro-spinal fluid was removed from A. W. on the 37th day of illness. A rhesus monkey was inoculated intracerebrally with 1 c.cm. while 12 mice were each inoculated intracerebrally with 0.03 c.cm. Of these mice four died 7, 10, 10, and 16 days later; histological examination of their brains revealed round-celled infiltration of the choroid plexus and meninges. The monkey remained normal for 8 days after inoculation; its temperature then rose to 104° F. and continued between 104° and 106° F. till it was killed on the 13th day after inoculation. During the whole of this time it exhibited no definite nervous symptoms but lost weight and was abnormally quiet. No naked-eye lesions were found at the post-mortem and no bacteriological growth was obtained in aerobic and anaerobic cultures made from the blood and brain. Blood-serum, brain, and liver tissue were inoculated intracerebrally into mice which died in 6-8 days with symptoms typical of lymphocytic choriomeningitis, while characteristic lesions were found in the central nervous system.

Virus obtained from the blood-serum of this monkey has been carried on for 18 passages in the brains of mice and has shown no diminution in virulence during these passages, the mice invariably dying 6-8 days after inoculation. Two rhesus monkeys were each inoculated intracerebrally with 1 c.cm. of a 20 per cent. suspension in saline of the brain of Monkey 1. Five and nine days later their temperatures rose above 104° F. Monkey 2 gradually lost weight and continued with a febrile temperature till the 10th day after inoculation. Its temperature then fell and it became weak in the hind legs, slight ptosis developed in both eyelids, and the monkey was killed moribund 14 days after inoculation. Monkey 3 ran a similar course and was killed 18 days after inoculation. 1 c.cm. of blood-serum from Monkey 1 was inoculated intracerebrally into Monkey 4. This animal showed a rise of temperature to 105° F. 4 days after inoculation and was killed 10 days after inoculation with symptoms identical with those of Monkeys 2 and 3. At death in all cases there were no characteristic appearances, though in Monkey 2 the liver was rather pale. Bacteriological cultures from the blood and brain were again sterile, but mice inoculated intracerebrally with liver, blood, brain, and adrenal all died in 6-8 days.

The symptoms produced by this (W) virus and its

distribution in these monkeys are identical with those obtained with the American strain of the virus of lymphocytic choriomeningitis.

Cerebro-spinal fluid obtained from A. W. on the 44th day of his illness, seven days after the first withdrawal, was also inoculated intracerebrally into mice and into a rhesus monkey but the results were entirely negative.

Cerebro-spinal fluid was obtained from B. C. on the 15th day of his illness. Twelve mice were inoculated intracerebrally with 0.03 c.cm. but only two died during the night 14 days later. The brains of these mice however showed histological changes typical of lymphocytic choriomeningitis.

A rhesus monkey (No. 5) inoculated intracerebrally with 1 c.cm. of cerebro-spinal fluid showed no symptoms till 14 days after inoculation when its temperature rose to 104° F. Till the 23rd day after inoculation a febrile reaction continued, then the fever gradually abated and the animal recovered. Blood-serum from the monkey inoculated intracerebrally into mice on the 17th and 25th days after inoculation contained virus, since the mice died in 6-8 days. The blood of the monkey was bacteriologically sterile. Blood-serum obtained from the same monkey 37 days after inoculation and inoculated intracerebrally into mice did not contain virus.

The virus obtained from the blood of this monkey has been carried on in the brains of mice for 13 passages. Both the W and C strains of virus were found to be pathogenic for guinea-pigs and rats. Guinea-pigs inoculated intracerebrally died in 9-22 days. The only symptoms due to the virus were gradual loss of weight, emaciation, and great muscular weakness. Rats died in 8-11 days with similar symptoms. Identical symptoms were produced in these species by intracerebral inoculation of the American strain of the lymphocytic choriomeningitis virus.

In addition to the rhesus monkey the crab-eating macaque *Macaca irus* has been found to be highly susceptible to intracerebral inoculation with both the English and American strains of the choriomeningitis virus. The following species do not exhibit any clinical symptoms following intracerebral injection of the virus: dog, ferret, hedgehog, field vole (*Microtus agrestis*), bank vole (*Evotomys glareolus*), rabbit, hen, canary, and parakeet. Wild mice are also susceptible to intracerebral inoculation; sufficient experiments have not yet been made to determine whether they may harbour the virus under natural conditions. Immune bodies may develop after inoculation, and the rabbit has been used for the production of immune sera. The virus may persist in the brain of the rabbit for at least 7 days.

HISTOLOGICAL LESIONS

The essential histological lesion in the nervous system was that of an acute leptomeningitis, particularly incident upon, though not confined to, the basal meninges, which produced an intense cellular exudation throughout the entire ventricular system. The lesions were similar in all the animals examined; they differed only in severity. Separate descriptions of the appearances seen in the various species would be redundant. The following description of the lesions in the nervous system of a guinea-pig inoculated intracerebrally with the English strain of virus (W) will suffice as an example:—

The meninges at the base of the brain were heavily infiltrated with cells. The infiltration extended over the cerebellum and for some distance over the posterior surface of the spinal cord, but did not extend over the vertex of the brain. The predominating type of cell

present was the small lymphocyte, though many polymorphonuclears and plasma cells were also seen. In some areas in the fourth ventricle a perivascular arrangement of cells was noted, and in that part of the medulla adjacent to the floor of the fourth ventricle there was engorgement of the smaller blood-vessels and slight perivascular infiltration. In sections of the brain which contained portions of choroid plexus there was an intense exudation of cells in between the choroidal cells, though these did not appear to be damaged by the infiltration. In general it may be said that the cells of the choroidal plexus were somewhat hypertrophied.

The iter of Sylvius contained many cells, whilst the cavities of the lateral ventricles were almost obliterated by cellular masses.

The brain tissue was little affected by these meningeal lesions. The only reaction of note was a proliferation of the marginal neuroglia in the tissue adjacent to the walls of the lateral ventricles. There was no microglial reaction; no changes in the neurones could be detected and there was no evidence of demyelination.

As regards the severity of the lesions in the different animals, these were most intense in mice and guinea-pigs inoculated intracerebrally with either the American or W strain of virus. In monkeys the lesions were much less striking. In Monkey 2, inoculated with W strain, the basal meninges only were affected, and these not to any great extent, but in the brain of a mouse inoculated with blood from this monkey the ventricular lesions were especially severe, the cells of the choroid plexus in the lateral ventricles being stuck together by masses of infiltrating cells, whilst there was much cellular infiltration of the meninges over the posterior aspect of the spinal cord.

No lesions could be found in the brain of a ferret inoculated with the W strain of virus. In rabbits there were a very small number of infiltrating cells in the meninges and choroid.

In only three mice have intranuclear inclusions been found resembling those described by Traub (1935) in guinea-pigs. These inclusions were found more especially in the cells of the choroid plexus and resembled in many respects those produced by the guinea-pig salivary virus. It seems extremely doubtful whether they are caused by the virus of benign lymphocytic choriomeningitis, since on rare occasions they have been found in the brains of apparently normal mice. The true significance of these acidophilic inclusions has recently been demonstrated by Thompson (1936). They are due to a virus found in the salivary glands of mice. On the other hand, as will be mentioned later, small granules are found in the cytoplasm of many mononuclear cells in the exudate.

In mice lesions are as a rule restricted to the central nervous system, though occasionally in the lungs there is evidence of a virus pneumonia while in the liver the Kupffer cells are swollen and prominent. In guinea-pigs and monkeys, more especially *Macaca irus*, the liver often exhibits fatty degeneration with areas of focal necrosis, accompanied by round-celled infiltration. Focal areas of round-celled infiltration are also seen in the suprarenals of monkeys, particularly in the cortex. In the kidneys the glomerular tufts are swollen as a result not so much of infiltration with round cells as of undue prominence of the endothelial cells; occasionally a few infiltrating cells are found between the convoluted tubules.

IMMUNOLOGICAL REACTIONS

Sera from A. W. and B. C. were found to contain virucidal antibodies not only against the homologous strains but against each other, the American strain and the N strain derived from English mice. Antisera were prepared in the rabbit against the American

and N strains. These sera were found to neutralise from 100 to 1000 M.L.D. (minimum lethal doses) of virus, whether of the homologous or heterologous strains. The monkey which recovered after inoculation with the cerebro-spinal fluid of B. C. was subsequently resistant to intracerebral inoculation with the American strain. The human strains isolated in this country are thus either identical or at any rate very closely related both to the American human strain and to the English mouse strain. A number of other human sera have also been examined during the course of these experiments. The results will be given in a further publication but a few details may not be without interest. The brother of A. W., for instance, who lived with him gave no protection, but his partner in the garage where he worked had immune bodies in his serum, although without a history of illness affecting the nervous system. The serum of a patient from Ireland whose history has recently been detailed by Collis (1935) protected both against American and English strains. This patient lived in an eighteenth century house overrun with rats and mice. Our thanks are due to Dr. W. R. F. Collis of Dublin for supplying this serum.

Serum from one of us (G. M. F.), who has carried out the animal experiments here described, fails to protect.

THE VIRUS

Filtration experiments with both the American and English strains show that the virus suspended in Hartley's broth passes through Berkefeld V filters, Chamberland L₁ and L₂ candles, and with difficulty through Seitz E or K discs or Berkefeld N filters. This finding would indicate that the virus is of comparatively large size. This is also borne out by the fact that by centrifugation for 3 hours at 10,000 revs. per min. it is possible to concentrate a considerable part of the virus in the deposit. Finally in experiments carried out in conjunction with Dr. R. D. Mackenzie it has been possible to demonstrate, in the cytoplasm of mononuclear cells from the brains of mice, rats, and monkeys infected with all strains of the virus, minute granules which stain purplish red with Giemsa, and are approximately of the same dimensions as the virus of herpes. These granules may be the actual virus. Agglutination and other experiments are at present being undertaken to investigate this question. The virus kept at 4° C. retains its activity for at least 10 days and at 22° C. for at least 6 days, although by this time a considerable part of the virus is destroyed.

DISCUSSION

The experiments here described show that from apparently healthy mice it is possible to obtain a virus which on intracerebral inoculation into monkeys, mice, guinea-pigs, and rats gives rise to a fatal infection associated with infiltration of the meninges and choroid plexus. The involvement of the central nervous system appears however to be only part of a more generalised infection, since the virus circulates freely in the blood stream. From the cerebro-spinal fluids of two patients with somewhat vague nervous symptoms following febrile reactions it has been possible to obtain a virus which in experimental animals behaves in the same way as that obtained from English mice. The three English strains also behave in the same way as a strain isolated by Armstrong from a case of benign lymphocytic meningitis in America. Serum from a patient in Ireland recovered from the same disease contains immune bodies to both the American and English strains of the virus. There is thus evidence that

this virus infection is widely spread on both sides of the Atlantic. The virus is excreted in the urine of mice and can pass with ease through the scarified skin, which may thus constitute the chief portal of entry in human cases though the virus may possibly enter also through the nasopharynx. The evidence here brought forward shows that a virus infection is present in mice and possibly also in rats and that this virus can be communicated to man. The exact portal of entry in human cases has not yet been determined but judging from analogies with infection by *Leptospira icterohæmorrhagæ* it is likely to be the skin or mucous membranes.

SUMMARY

1. A virus has been isolated from the cerebro-spinal fluid of two patients suffering from obscure nervous symptoms associated with an increase of lymphocytes in the cerebro-spinal fluid.

2. The virus inoculated intracerebrally into monkeys, mice, rats, and guinea-pigs causes a fatal infection; post mortem there is intense infiltration of the meninges, choroid plexus, and ventricles with round cells.

3. When inoculated intraperitoneally into mice the virus causes no symptoms but remains for some weeks in the spleen and kidneys. It is excreted in the urine of mice and can pass through the lightly scarified skin.

4. A similar virus has been isolated from apparently healthy mice.

5. The human and mouse strains isolated in this country behave in animals in the same way as the American virus described by Armstrong.

6. Sera from human cases in this country contain immune bodies to the American virus and to the English mouse strain virus.

7. Certain of the properties of the virus are described and the mode of infection discussed.

Our thanks are due to Dr. Charles Armstrong, of the United States Public Health Service, for his kindness in supplying us with a strain of the virus isolated by him. We also desire to thank Dr. Purdon Martin and Dr. Gordon Holmes for permission to investigate and to publish details of the patients under their care, and Dr. D. F. Rambaut for allowing the investigation of pathological material to be carried out in the laboratory of St. Andrew's Hospital, Northampton.

IDIOPATHIC DILATATION OF STENSON'S DUCT

BY REGINALD T. PAYNE, M.D., M.S. Lond.,
F.R.C.S. Eng.

CASUALTY SURGEON, ST. BARTHOLOMEW'S HOSPITAL
CURATOR OF MUSEUM, ST. BARTHOLOMEW'S
HOSPITAL MEDICAL COLLEGE

DILATATION of Stenson's duct in the absence of obstruction or infection is an unusual condition. In the former group of cases the obstruction is invariably due to a calculus, and in the latter the dilatation is associated with recurrent pyogenic parotitis. The case now reported differs from both of the foregoing types in being associated with neither obstruction nor infection; and in the absence of exact knowledge as to the underlying pathology it can only be regarded as possibly due to achalasia of the duct orifice.

CASE RECORD

The patient, a surgeon aged 51, first came under my care in May, 1934, on account of recurrent swelling and dilatation of the masseteric and buccal portions of the right parotid duct. These symptoms had started some two years previously and on the first occasion developed while the patient was operating. Since then he had never been free from the trouble. The swelling of the duct often occurred in the earlier part of the day, at times developing whilst the patient was drinking a cup of tea. On the whole the symptoms were particularly prone to develop during work demanding concentrated effort such as operating or putting up a fracture. The attacks had at times been induced by pipe-smoking and occasionally by emotional stress. When the swelling developed it could be felt as a small oval tumour in the line of the right parotid duct, and it was accompanied by discomfort rather than actual pain. The patient had learnt to relieve his symptoms by pressure over the swelling which immediately led to its disappearance and was followed by a gush of saliva into the mouth. On operating days this manœuvre was carried out between operations in order to keep free from discomfort. At no time had there been any swelling of the parotid gland itself and there were no symptoms referable to the other salivary glands.

Past history.—The patient had had a hæmoptysis at the age of 21, and on this account went to live abroad. Shortly after this he had a mild attack of uncomplicated typhoid fever. He had never suffered from mumps or any other disease of the salivary glands. There was no history of hay-fever, asthma, eczema, or other allergic manifestation. In 1931 he had new dental plates which never fitted very accurately, and the swelling of the right parotid duct started a year after this. His general health had been good but he was very highly strung and for some years had persistently overworked.

PHYSICAL SIGNS

The patient was a healthy, active man of sparse build. On examination of the right cheek when the swelling had developed a diffuse fullness could be seen in the line of the parotid duct in its masseteric and buccal portions. On palpation the parotid gland was not enlarged or tender but the distended duct could be felt as an ovoid tumour $1\frac{1}{2}$ in. long and $\frac{1}{2}$ in. wide at its widest part, reaching from the hilum of the gland to the duct orifice. The distended duct was slightly tender and pressure over it gave rise to a gush of saliva into the mouth. There was no abnormality to be made out after the duct had been emptied in this way. The orifice of the duct in the mouth was natural, there was no evidence of any local scarring, and the surrounding mucosa was normal. Its appearance was in every way identical with the orifice of the left parotid duct. The other salivary glands, their ducts, and the duct orifices all appeared natural. The patient was edentulous and the condition of the buccal mucosa was healthy.

Saliva.—A catheter specimen of saliva from the right parotid duct was profuse, clear, and free from mucus, and its diastatic content was 20,000 units. A Gram film showed an occasional epithelial cell of pavement type in some of the fields but no organisms were present and cultures were sterile.

Skiagrams and sialograms.—Skiagrams showed no evidence of a parotid calculus. Sialography was carried out and the resulting pictures are shown in Figs. 1 and 2.

FIG. 1.—Right sialogram showing a marked degree of dilatation of the buccal portion of the parotid duct.

Fig. 1 shows much dilatation of the buccal portion of the duct and Fig. 2 shows this condition together with dilatation and segmentation of the masseteric portion of the duct. Several attempts were made to get the lipiodol to pass into the intraglandular ducts, but without success. This was presumably due to some valve action in the interior, the mechanism of which was also responsible for the absence clinically of involvement of the intraglandular ducts in the swelling.

OPERATION

Under general anaesthesia the terminal $\frac{1}{4}$ in. of the duct was excised together with $\frac{3}{4}$ in. of its inner wall. The resulting cavity was packed with gauze. Irrigation followed by dilatation with small sinus forceps was carried out twice daily after operation and the wound kept lightly packed with gauze. The patient's jaw was bandaged and the diet was restricted to fluids. Healing of the mucosa was completed in about eight days, after which dilatation was carried out with canaliculus probes, daily at first and then at increasing intervals for a period of six weeks. No swelling of the parotid gland occurred after operation and the patient has remained free from symptoms since then.

COMMENT

Recurrent swellings of the parotid gland may be due to a variety of causes, including calculi, infections, drugs, &c. Recently Pearson¹ has investigated these conditions in children and in the light of some of the evidence has suggested that there is a relationship between certain types and allergic manifestations such as eczema and hay-fever. The sudden appearance and disappearance of the parotid swellings in some cases and the occasional history of a familial tendency have led other workers to arrive at similar conclusions.

The case now recorded differs from those referred to above in that the parotid gland itself was never involved, the swelling being entirely confined to the duct. The condition was not associated with any known allergic phenomena, but tended especially to occur during concentrated effort or as the result of some emotional stress. Clinical investigation demonstrated the absence of infection of the saliva

and also showed the degree of dilatation of the duct. Jemtel² records a very similar case occurring in a boxer of 25. This patient developed a swelling of the parotid duct whenever he ate anything. Investigation showed a condition identical with that in the case now recorded, and a similar operation was performed with equally satisfactory results. A somewhat similar case in a man of 70 is recorded by

FIG. 2.—Right sialogram, after further injection of lipiodol, showing much dilatation of the buccal portion of the duct, together with dilatation and segmentation of the masseteric portion of the duct.

Bársony.³ In this case the swelling appeared during every meal and disappeared after massage, but the duct orifice was enlarged and the dilatation of the duct involved some of the intraglandular ducts.

The clinical evidence in the case now reported suggests that the pathological dilatation of the parotid duct was secondary to the failure of relaxation of the duct orifice. The conditions under which the swelling occurred suggest that some neuromuscular incoördination in a gland under the control of the parasympathetic system was a causal factor. If this is the case the condition bears some resemblance to achalasia of the cardia. In the present case recovery followed the operation described.

PRIMARY INTRAHEPATIC CARCINOMA OF THE BILE-DUCTS

BY REX BINNING, M.R.C.S. Eng.

HOUSE PHYSICIAN AT ST. GEORGE'S HOSPITAL, LONDON

AN unmarried woman, aged 46, a cook, was admitted to St. George's Hospital complaining of abdominal pain and vomiting of three weeks' duration.

She had had slight indigestion and vomiting for the previous three months. The pain was severe, constant, and was not relieved by taking food, but it was somewhat eased by flexing the trunk. One week before admission she had a slight hæmatemesis. She was constipated and sometimes passed bright red blood on defæcation. There were no abnormal urinary symptoms. She said that she had vomited bile occasionally and had had attacks of jaundice, which lasted only 24 hours. In two months she had lost a stone in weight. There was nothing of

importance in her past history or in her family history. She had travelled extensively in Egypt and Syria, but had contracted no diseases while abroad.

On admission to hospital on Nov. 23rd, 1935, the temperature was 97.5° F., pulse 105, and respirations 23 per min. She was pale and weak in appearance, but not wasted. The abdomen was distended, particularly in the upper half. She was very tender in the right hypochondrium. The liver extended downwards 3 in. below the costal margin and was tender; the gall-bladder was palpable below the liver. There were some recently inflamed external piles and the rectum contained soft fæces. The bases of the lungs were slightly dull to percussion; the heart was normal. A blood count showed: red cells, 5,160,000; hæmoglobin, 74 per cent.; leucocytes, 9920; colour-index, 0.64; polymorphs, 74 per cent.; lymphocytes, 20 per cent.; mononuclears, 8 per cent.; eosinophils, 5 per cent.; basophils, 1 per cent. The sedimentation-rate by Westergren's method was 24 units in the first hour. The Wassermann reaction was not quite negative. The diastase index of the urine was 200 units, or about 10 times the normal. Skiagrams taken on Nov. 26th showed a group of abnormal shadows in the gall-bladder region, possibly due to gall-stones. There was nothing abnormal shown in the lungs. An opaque meal was given on Nov. 28th, and skiagrams showed the gall-stone opacities and gastritis, but no other organic lesion; the gastric emptying time was normal and no lesion was detected in the large intestine. A further skiagram of the chest on Dec. 4th showed that the right diaphragm was much raised and there was a small right pleural effusion.

The patient became worse and progressive enlargement of the liver was observed. She was in constant pain. She died on Jan. 5th, 1936.

Autopsy showed that the abdomen contained 1½ pints of fluid. The liver was greatly enlarged and weighed 15 lb. and the diaphragm was pushed up on the right to the level of the third rib. There was a diffuse carcinomatosis of the liver, especially of the right lobe, with enlarged glands at the hilum and in the gastro-hepatic omentum. The gall-bladder contained one large stone and many small ones. There were no pathological changes of importance in the rest of the body, and no evidence of metastasis or other growth was found. Sections were cut of the liver and the glands taken from the gastro-hepatic omentum. The sections of the liver showed extensive infiltration of adenocarcinoma. The cells resembled those of the bile-ducts and were cylindrical in shape, tending to become ellipsoid in some parts of the sections; there was no evidence of cirrhosis. The sections of the glands showed infiltration with similar cells.

Multiple carcinoma of the intrahepatic bile-ducts is uncommon. It is estimated that primary carcinoma of the liver accounts for only 0.5 per cent. of all cancers, and different authorities consider that 14–32 per cent. of primary carcinomata of the liver arise from the bile-ducts.¹ Bile-duct carcinoma is associated with cirrhosis of the liver in 50 per cent. of the cases,² and is more common in women.³ There is jaundice in 60 per cent. and ascites in 58 per cent.

This patient, therefore, presented certain uncommon features. There was no evidence at autopsy of cirrhosis of the liver, though there were several clinical signs suggestive of it. While she was in hospital jaundice was absent but there was a history of very slight attacks some months previously. She was considerably younger than is usual in this disease.

I should like to express my thanks to Dr. A. Feiling for permission to publish this case, to Dr. John Taylor for the report of the autopsy, and to members of the radiological, bacteriological, and biochemical departments of St. George's Hospital for carrying out the various investigations in the case.

FISTULA-IN-ANO *

By J. P. LOCKHART-MUMMERY, F.R.C.S. Eng.

EMERITUS SURGEON TO ST. MARK'S HOSPITAL FOR DISEASES
OF THE BOWEL, LONDON

THE treatment of fistula-in-ano has a very ancient history. Reference to it can be found in all the earliest medical MSS. and what is probably the very first medical treatise on a special subject is a treatise on "Fistula-in-Ano," by John Arderne, which was found in a fifteenth century manuscript. Louis XIV., le Roi Soleil, was operated on for a fistula in 1687, and it was recorded his surgeon received the magnificent fee of £6000 for making a success of the operation.

THE CAUSES OF FISTULA

Foreign bodies.—It has been generally supposed until quite recently that most fistulæ arise as the result of injury from foreign bodies which have been swallowed. Undoubtedly a small percentage of fistulæ are so formed and there is a collection in the museum of St. Mark's Hospital of foreign bodies which have been removed from fistulæ. They consist mostly of haddock spines, rabbit bones, pieces of wood and metal, and seeds. But I think it is very doubtful whether more than a very small proportion of fistula are so caused.

Fissures and ulcers of all kinds in the anal region may result in fistulæ and abscess. A small neglected fissure is liable at any time to penetrate the muscular wall of the rectum, when a small direct fistula will generally result in an internal opening at the base of the fissure.

Suppuration of the anal glands is probably the most common cause of all fistulæ. These anal glands, until quite recently, appear to have been overlooked by anatomists. They occur near the lower part of the anal canal as tubular, branching structures, lined with transitional epithelium. They pass into, or through, the muscular coat of the bowel and end in the connective tissue. In some cases they can be seen to pass through the circular muscle coat of the internal sphincter and terminate in the ischio-rectal fossa. Very careful microscopic sections, cut in series, of the anal region generally demonstrate the presence of several such glands. Their composition and numbers are erratic, and they seem to serve no particular purpose. They correspond to the odoriferous glands in animals which act as a sex attraction to the male. They are very well marked in the rabbit, pig, and chicken. The ducts of these glands open into the bases of the crypts of Morgagni. Connecting as they do with the bowel lumen, these vestigial glands act as a path for infective organisms to reach the connective tissue and set up an abscess.

Dr. C. E. Dukes was able to actually demonstrate in 1931 that a case of fistula in St. Mark's Hospital was due to suppuration in one of these glands. Careful dissection of the fistula revealed that the track was lined with the transitional type of epithelium of which the glands are composed. This case was published by Sir Charles Gordon-Watson.¹ These findings have since been confirmed by other observers, notably by Dr. Tucker and Dr. Hellwig.²

Just as appendicitis is due to inflammation occurring in a vestigial organ, the appendix vermiformis, so fistula-in-ano is caused by a suppuration occurring in these vestigial sex glands.

Congenital cysts, as a cause of fistulæ, are much commoner than is generally supposed, and at St. Mark's Hospital quite a number of them are seen in the course of a year; even as many as two cases have been operated upon in one week. These cysts are an exaggeration of the post-anal dimple, which is found in some 20 per cent. of human beings. Patients are, of course, born with these cysts, but they seldom give trouble until adult life, when, possibly as the result of their rapid growth or of injury, they start to suppurate and an abscess forms. They may be detected easily, as they always occur in exactly the same place, just over the tip of the coccyx in the middle line. A very careful examination will generally reveal hairs projecting from the opening of the sinus, and when these hairs are seen it is quite conclusive.

These cysts have had a bad reputation in the past because their true nature has not been recognised and they will not heal up until they are completely cut out. As the tracks are lined with epithelium the cysts will reform unless every part of the cyst wall is removed. When completely cut out they, of course, give no further trouble. Sir John Bland-Sutton was the first person to recognise their true significance. They are due to faulty coalescence of the skin during early embryonic life and are true sequestration dermoids. They have no connexion whatever with the rectum.

Tubercle is the cause of fistula in about 20 per cent. of all cases. Tuberculous fistulæ can be fairly easily distinguished from ordinary fistulæ by their clinical appearances. There is very little induration of the tissues, the skin is undermined and of a blue or purplish colour, and the discharge is a thin serous one rather than ordinary pus.

The vast majority of cases of tuberculous fistulæ are secondary to phthisis of the lung, and the infection has no doubt reached the rectum as the result of sputum being swallowed. In a few cases tuberculous fistulæ may be primary, and in such instances the infection has probably come from the gut, as we know that tubercle bacilli are not infrequently to be found present in the fæces of people who have not got any clinical signs of tuberculosis. It is quite useless to test the pus from a fistula for tubercle bacilli, as it is seldom found even in cases where there is no question about the diagnosis.

There are two methods of proving the presence of tubercle in these fistulæ. One is to make a very careful microscopical examination of a piece of the wall of one of the tracks, the slides being stained by the Ziehl-Neelsen method and searched for tubercle bacilli; the other method is to inoculate guinea-pigs.

A portion of the wall of the fistula is cut up in small pieces and treated with antiformin. This destroys all the other micro-organisms but leaves the tubercle bacilli intact. After three hours the material is washed with a sterile salt solution, centrifuged, and the residue injected into the abdominal wall of the guinea-pig. At the end of six weeks the guinea-pig is killed and examined for caseous nodules.

Injury and trauma.—Some of the most serious and most troublesome fistulæ that I have been called upon to treat have been due to the injection treatment of piles. It is only fair to say that in all these patients—and there have been quite a number—the treatment has been carried out badly, and in most of them urea-quinine hydrochloride has been used for the injection instead of carbolic. There has been no case of fistula in St. Mark's Hospital as the result of the injection treatment of piles, to my knowledge, in spite of the fact that some 80

* A post-graduate lecture delivered at St. Mark's Hospital on Feb. 6th, 1936.

injections a week are given here. When the treatment is carried out inexpertly, however, an abscess may result, and this is likely to lead to a very bad type of fistula. I had a patient recently who had to have five operations and it took over a year before the condition was healed; one track went up to the promontory of the sacrum.

Another cause of traumatic fistula, of which I have seen several cases in the last few years, is the treatment of rectal carcinoma with radium. The insertion of radon seeds or radium needles in the neighbourhood of the rectum is very liable to set up an abscess, and a fistula results. These cases are particularly troublesome, as, owing to the action of the radium, there is very great difficulty in getting the parts to heal. No attempt can be made to do more than just provide adequate drainage to the infected tissues.

TREATMENT

In practically all cases the initial lesion is an abscess of which the fistula is a secondary development. If the initial abscess is opened at the earliest possible opportunity and free drainage established to the exterior, or into the bowel, about 70 per cent. of such abscesses will heal without resulting in a fistula. For this to occur it is necessary that the abscess should be opened before there is any large accumulation of pus and within at least 30 hours of its formation. Very free drainage, also, should be provided and the cavity should not be packed with gauze or any foreign body introduced. This method of draining abscesses was advocated by me in 1923³; it has now been used in St. Mark's for a number of years and is found to greatly reduce the incidence of fistula. It consists of cutting away the skin over the abscess cavity so as to leave a large opening and applying a wet compress to the outside. No packing is used, nor any drainage introduced, and there is no interference at all with the interior of the abscess. Too often what happens is that the abscess is left until it bursts through the skin, or into the bowel, or else an inadequate opening is made into it. Once a fistula has formed there is only one method of treatment that can be effective—namely, an operation to lay open and drain all the tracks.

A certain proportion of fistula can be cured by quite a simple operation, but I have no hesitation in saying that very many require considerable experience and much skill, if satisfactory healing is to be obtained, and that of all the cases which come into St. Mark's Hospital for treatment the fistula cases are the most difficult, and I am not excluding excision of the rectum for cancer. Hardly two are alike and each requires special study. A fistula operation is not a major operation and should never endanger life, but it is very far from being a minor one. More surgeons' reputations are damaged by unsuccessful operation for fistula than by laparotomies. The bad results of laparotomy are generally buried with flowers, while the fistulæ go about the world exhibiting the unsuccessful results of the treatment.

While it is impossible to describe any one method of operating for fistula, since there is too much variation in the conditions found, there are nevertheless certain broad principles involved in successful treatment which deserve our serious consideration. None of the many attempts that have been made to classify fistulæ is, in my own opinion, satisfactory, nor can they ever be, since fistulæ-in-ano do not lend themselves to any satisfactory classification. There is an infinite variety.

PLANNING THE OPERATION

Our object in operating upon any fistula is to obtain sound and permanent healing in the minimum time and with the least inconvenience to the patient. The first consideration, however, is to obtain good, sound healing, and although this can be occasionally secured when the patient is allowed to walk about this is seldom worth attempting, and I prefer to have the patient in bed during the whole period of convalescence.

The first principle involved in curing a fistula is to provide free drainage to all the fistulous tracks. It is, however, not sufficient to provide drainage at the time of the operation, but so to plan the wound that free drainage can be maintained during the whole period of healing. In dealing with a fistula wound we are forced to make use of healing by granulation, since healing by first intention is not possible, and a proper understanding of how to get sound healing by "third intention," as it is often called, is essential to success. All tracks must be freely opened up, but if the fistula is very extensive or goes very deep, it is often inadvisable to do this all at one sitting, as it may involve too extensive damage to the muscular structures, or lead to deformity of the parts. Hence, it is often better to plan the operation in several stages.

When complete division of all the tracks will involve complete division of the external sphincter, the operation should always be performed in two stages, the division of the muscle being left to the second stage, when the remainder of the wound has to a large extent already healed. There is usually, one might almost say always, a track opening into the anal canal, what we call the internal opening, but in only a minority of patients does this open above the external sphincter, and its division, therefore, involve division of this muscle. However many external openings there may be it is almost an invariable rule that there is only one internal opening, and it is well to bear that in mind. In most cases this internal opening is in the midline and usually posterior.

When possible the wound should be so planned that the portion of it involving the skin is considerably wider and larger than the portion involving the mucous membrane and the bowel; this will often require what at first appears to be an unnecessarily large wound. When operating at St. Mark's I have often found that onlookers have been surprised at the amount of skin which I have cut away, no less than at the fact that the sphincter muscle has not been cut at all. The object of cutting away so large a proportion of skin is to provide a free opening to the fistulous track, which will remain a free opening until the track itself is healed.

A very common mistake in operating for fistula is to miss one of the main tracks, and when this happens it invariably leads to failure. The track that is most commonly missed, in my experience, is that passing across from one ischio-rectal fossa to the other, behind the anal canal. This is often present even in a fistula which appears at first to be confined to one ischio-rectal fossa only; it may also occasionally be multiple.

We have first to satisfy ourselves that we have laid open all the tracks, and for this purpose the eyes and fingers are the best guide. I have found that radiograms with Lipiodol and the injection of the fistulous tracks with dyes are most misleading and do not help. When the parts are laid open

it is usually quite easy, if one has experience, to detect the openings of unsuspected tracks or to feel them with the fingers.

The next thing is to decide whether we are going simply to leave the wound open to granulate, or if we should remove all the fibrous tracks. If the latter can be done successfully, healing will be sounder and much more rapid than if the dense fibrous tracks are left, since they are naturally composed of poor healing material. The decision will depend upon the knowledge and skill of the surgeon, but he must bear in mind that it is quite useless to remove only part of the tracks. When the tracks are very extensive and extend very deeply it is usually impracticable to remove them without the danger of damaging the muscular apparatus, or the rectum itself. When this is the case the wound should be simply left to granulate, being carefully, but very lightly, packed with wool or ribbon gauze. Wool is better as a rule, since being unwoven those fibres that become involved in granulation tissue can be left and the remainder washed out. While a woven material will all have to come away in one piece, and the granulating wall most certainly damaged, which is what we wish to avoid. To allow the granulation wall to form packing should be left undisturbed for at least three days and then soaked out in a bath, after which it should be changed twice a day, great care being taken to pack the wound lightly and not to damage the healing surfaces.

If the surgeon decides that it is feasible to remove all the fibrous tracks, this should be done. The first finger of the left hand should be kept in the rectum to act as a guide and prevent accidental damage to the bowel or the musculature. Every bit of fibrous track should be dissected out with the greatest care so as not to leave anything but healthy fat. Bleeding points should, if possible, be twisted rather than ligated, as healing will occur much better if foreign bodies in the form of catgut are not left in the tissues. If ligatures have to be used, they should consist of the finest catgut only and should be as few as possible.

Having completed the operation the wounds should all be well swabbed out with strong Monsol or some other suitable antiseptic. A good area of skin should be removed in order to leave really free drainage, and a wet antiseptic compress applied outside. As a rule no packing at all should be inserted, as we want the whole wound to collapse and the fatty walls to adhere to each other. The wound must be carefully watched daily during the next few days to see that no pockets, or residual cavities, have formed in the deeper parts, but on no account should a probe be used. A finger can be passed into the rectum and the deeper part of the wound squeezed to see if any cavity is left. If a track, or a cavity is discovered, it must be lightly packed and treated in the ordinary way. If the treatment is successful it will be found that instead of a deep wound or wounds, there is only a large and quite superficial one, which heals up rapidly without much trouble. A very great saving of time can often be obtained by this method of operating, as even if only the deeper parts heal by first intention the resulting wound will be smaller and heal more easily than if treated in the more orthodox manner.

The after-treatment of a case of fistula is most important and personally I do not undertake to operate for a fistula unless I can supervise the after-treatment myself. Dressings should be changed twice daily at first, and the patient should soak himself in a hot bath before removal of the dressings. Antiseptics

should be discarded after the first three or four days and the wound should be lightly packed with gauze or wool soaked with castor oil.

TREATMENT FOR SPECIAL KINDS OF FISTULA

In a fistula where the internal opening is to one side and the division of the track will involve dividing the external sphincter, the operation should always be done in two stages. The track leading to the internal opening is not divided until the external wound has healed down to it.

Submucous tracks running up the bowel should be divided into the rectum and the edges trimmed away to give good and sufficient drainage. This is not difficult, but there may be some trouble in controlling the bleeding if the track passes high up the bowel. These tracks can be divided with a cautery, or the bleeding controlled by a large tube in the rectum, and by packing. In a few cases it may be necessary to make use of the elastic ligature to divide such tracks owing to the impossibility of controlling the bleeding if they are divided with a knife.

Very high tracks which pass outside the muscular coat are fortunately very unusual. When they do occur they are the cause of much anxiety as they are very difficult and sometimes impossible to deal with adequately. They cannot be completely laid open into the bowel, as they would involve too much damage to the musculature. As free drainage as possible should be provided for and the deep parts of the wound drained with tubes suitably disposed. They may sometimes be healed by injecting the deep tracks with acriflavine in anhydrous glycerin, or of silver nitrate grs. 20 to the ounce.

Tuberculous fistulae.—The treatment of these patients should be on conservative lines. It is useless to expect healing of a tuberculous fistula in a patient who is losing weight and suffering from active tubercle in the lungs or elsewhere. If there is not satisfactory drainage of the tracks this should be established by the simplest method and the patient at once sent to a sanatorium or put under proper conditions of fresh air and sunshine, the local treatment being entirely subordinate to the general treatment for tubercle. When the patient's general condition has improved, and he is putting on weight and is in a good state of resistance, the fistula can be treated in the usual way. As there is always a risk of spreading the tuberculous infection into healthy tissue or to other parts of the body by the lymphatics, it is better to use a diathermy knife or an actual cautery rather than a scalpel.

Sacrococcygeal fistulae.—The only thing necessary to get satisfactory healing is to excise all the tracks completely right down to the fascia overlying the bone. The wound should be left open to granulate.

When the fistula wound shows signs of not healing, the first thing to do is to examine it very carefully to make sure that there is no fresh track or one that has been missed, and to make sure that there is free drainage. A properly healing fistula wound should show no obvious pus after the first week and the presence of pus generally indicates a deep and unnoticed track or bridging in some part of the wound. Poor or insufficient drainage is usually the cause of the trouble and should be remedied by laying the wound open again. Too tight packing is sometimes the cause; all packing should be as loose as possible.

At a special hospital like St. Mark's we not unnaturally get some very bad cases of fistula. The cases which have been unsuccessfully treated

elsewhere are frequently sent here and such cases come from all over the world. Many of them are real problems and require most careful treatment, but I am thankful to say that we are almost invariably able to send them home cured in the end.

A CASE SHOWING AN UNUSUAL RELATIONSHIP BETWEEN ASTHMA AND EPILEPSY

BY KATHLEEN COSTELLO, B.A. Sydney, M.R.C.S. Eng.
ASSISTANT MEDICAL OFFICER, LINGFIELD EPILEPTIC
COLONY; AND

J. TYLOR FOX, M.D. Camb., D.P.M.
MEDICAL SUPERINTENDENT OF THE COLONY

X. Y. was born in January, 1921. There is no record of either epilepsy or asthma in the family history. At the age of 10 she began to suffer from asthma, accompanied by bronchitis, and also from epilepsy. From the first, according to the father's statement, the fits always occurred at the end of the asthmatic attack. X ray examination at Guy's Hospital was negative, and there was no evidence of tuberculosis. The patient spent several months at the Downs Hospital.

She was admitted to the Lingfield Epileptic Colony in November, 1933. At that time it was stated that the

dyspnoic attacks were increasing in frequency, and the more severe ones were terminated by a major epileptic fit. At the time of admission the general condition of the patient was poor. No abnormality in the central nervous system was found. The chest wall was thin and there was a depressed sternal sulcus. Posteriorly there was relative dullness at the right apex and left base, with tubular breathing at the left apex. A few scattered crepitations were heard, especially in the left axilla.

For the first few months after admission there was persistent cough with fairly frequent attacks of definite dyspnoea at night. Six of these attacks, which were more severe than the rest, ended up, when the patient was very cyanosed, with typical epileptic fits. In the summer of 1934 the bronchitis cleared up and the asthma ceased. The signs in the chest, which had varied a good deal from time to time, disappeared. The patient began to gain weight rapidly and is now fat and healthy. There has been no recurrence of the epileptic attacks. From the first treatment was directed to the alleviation of the chest condition, and no medicine was given to control the fits.

A good deal has been written about the connexion between epilepsy and asthma, and it has often been suggested that they are both allergic manifestations. In some cases where they coexist it seems that the two types of attack may replace each other. In one case at present at Lingfield it certainly seems that when the fits are frequent the asthmatic attacks are fewer, and vice versa.

But so far as we know a case of this kind, when the epileptic fits only occur at the culmination of severe attacks of asthma, when there is considerable cyanosis, has not been reported before. With cyanosis, no doubt, the cerebral cells have insufficient oxygen, but other clinical conditions which cause cyanosis do not also cause epileptic fits.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF OTOLOGY

At a meeting of this section on March 6th, under the presidency of Mr. HAROLD KISCH, a discussion on

Disturbances of Function of the Ear Following Injury

was opened by Dr. G. KELEMEN (Budapest) who divided injuries into (a) those in which the petrous bone shared in general damage to other parts of the skull, (b) those in which the injury was limited to a disturbance of the sense of hearing or that of equilibrium. During the late war, he said, the former group was frequent; in peace time the latter were the more prevalent. In recent years disturbances of hearing and equilibrium had been studied in factories where both faculties were endangered. The consequences were divisible into (1) those in which secondary inflammation was the important factor, (2) those in which the injury of the terminal nerve organ was not complicated by inflammation, or at least where the associated suppuration was not the most important factor. For insurance or forensic purposes injuries of the ear were classified according to their symptoms; for diagnosis and treatment according to their localisation. The commonest fractures were longitudinal in front of or behind the pyramid; they might cross the labyrinth and, out of sight of the otoscope, involve important parts of the sense organs. Fractures might also present a route for intracranial complications via the internal auditory meatus.

In most cases the line of fracture was independent of the direction of the blow and of the site of the injury. It descended from the squama to pass round the capsule of the labyrinth. The eighth nerve might be injured (1) at its commencement in the narrow interosseous channels, (2) later where it ran, more loosely, in the internal auditory meatus, (3) in a funnel-shaped cavity, sometimes with a spur of bone narrowing the opening. It was at this narrowed spot that the nerve itself was apt to suffer damage; in other parts of its course the injury might be perineural. Inflammatory disease of the ear was of many varieties, from the simple otitis of the new-born infant to the formation of cholesteatoma. Bleeding between the layers of the tympanic membrane might detach the inner layer from the handle of the malleus; it did not necessarily lead to perforation. Injury might cause cysts, secondary inflammation in which led to development of the cholesteatomatous sac.

A splinter of bone under the intact skin of the meatus might be taken for a simple swelling of soft parts, when it really implied a fracture. A skiagram was apt to mislead unless taken from various angles. The tegmen tympani lay so close to the facial nerve and its geniculate ganglion that a fracture in this region might easily involve that nerve. Hæmorrhages in the cochlea might result in disturbance of hearing like tinnitus, or in deficient perception of certain notes. Defective hearing was frequently observed in association with injuries to the head, as Kisch pointed out, even when visible signs of fracture of the skull were lacking. Fracture of the tegmen might involve the dura and endocranium. Patients might die of meningitis months after

apparent recovery from fracture of the base of the skull. More radical measures were required for traumatic than for non-traumatic suppurative cases. Lesions due to trauma were serious in proportion to the degree of secondary inflammation; treatment should be on general principles.

Mr. E. D. D. DAVIS said that in compensation cases following motoring accidents disturbances of the function of the ear were frequently seen. He confined his remarks to internal ear or nerve deafness. The difficult cases were those of alleged concussion deafness, in which it was assumed there was an internal ear, labyrinthine, or nerve deafness arising from the concussion associated with head injury. In civil life nerve deafness as a result of injury was in his experience rare. Lannois and Chavanne reported that in 262 cases of simple labyrinthitis only 5 per cent. had almost total and apparently incurable deafness. The drum mechanism acted as a protection against the effect of explosions on the internal ear. During the late war, when ear injuries were common, cases of nerve deafness were divided into three groups: (1) with structural and permanent damage to the internal ear, (2) psychical or functional deafness, (3) temporary deafness. Cases in group (1) showed evidence of severe injury, such as bleeding from the ear, escape of cerebrospinal fluid, prolonged loss of consciousness, paralysis of cranial nerves, particularly the facial, and other brain injuries. There was tinnitus and vertigo, and obvious trauma of the ear. The deafness was permanent with loss of perception of high notes. X ray photography might show a fracture involving the labyrinth. Group (2) included patients who feigned deafness and even loss of voice; there were unexplained nervous phenomena, contradictory results from hearing tests, and no keen desire for recovery. There might be definite opposition to examination, and the structure of the ear showed no sign of injury. Group (3) consisted of cases of temporary deafness regarded as due to concussion, shock, or explosion. After a few weeks' rest these cases usually recovered. If genuine deafness remained after six months it was usually permanent. Many cases of shell concussion recovered rapidly. Well-marked cases of concussion deafness showed exaggerated reflexes, tremors, vasomotor disturbances, vertigo, and headache. Absence of signs of trauma to the ear and a normal caloric reaction in the labyrinth indicated the temporary nature of the deafness. A forgotten inflammatory or other ear disease, especially otosclerosis, might be revealed by scarring and opacities of the drum. In compensation cases Mr. Davis urged that medical witnesses on both sides should meet and try to agree as to the nature of the case. A ruptured drum required rest in bed, without local treatment; the meatus was cleaned and the ear left alone.

Mr. HERBERT TILLEY referred to the case of a man, aged 69, who was standing on a railway platform when an engine near emitted a shrill shriek; he put his hands to his ears and said it felt as if a knife had been stuck into each ear. There was tinnitus for a short time, but no vertigo. The deafness following had been extreme, and he felt it greatly as he was very musical. He found difficulty in carrying out the duties of his post. The insurance company denied that it was an accident and disclaimed responsibility.

Sir JAMES DUNDAS-GRANT said that cases of concussion often were benefited by small doses of perchloride of mercury.

Mr. SYDNEY SCOTT, referring to a statement that not more than 5 per cent. of cases of fracture of the

base had nerve deafness, said the probable reason of that small proportion was that many cases of fracture of the petrous bone were fatal. One such patient of his, however, survived for 20 years. He was a railway guard who was flung from one end of his van to another and was concussed. There was deafness with absolute loss of labyrinthine reactions, and bilateral rupture of the auditory nerve was diagnosed.

Mr. E. DEACON said that in a series of 230 cases of fracture of the skull 33 survived, and of the latter 11 had an acute suppurative condition of the ear. On 5 of them he performed the operation for acute mastoid disease. There was no tinnitus and no vertigo.

OTOSCLEROSIS ASSOCIATED WITH BLUE SCLEROTICS AND FRAGILITAS OSSIUM

Mr. T. RITCHIE RODGER referred to a case shown by Mr. Cleminson in 1926. Ten years before that van de Hoeve and de Kleijn had pointed out the frequent association of otosclerosis with blue sclerotics and imperfect osteogenesis. Julia Bell found that 60 per cent. of adults with blue sclerotics were deaf and the same proportion had fragile bones, while 44 per cent. had both. Inheritance was usually dominant, but there were exceptions. There was no such sex preference as was found in otosclerosis, but affected females had a slightly higher percentage of affected offspring than a corresponding number of affected males. Otosclerosis did not develop until the third decade, and transmission was generally direct; in one of his families two generations were skipped. Cockayne believed that both mesodermic and ectodermic defects were determined by a single dominant gene. The sella turcica seemed to be contracted, as if the pituitary body had not developed properly. There were often deformities apart from fractures. The deafness and the changes in the petrous bone were typical of otosclerosis. Mr. Rodger wondered whether the inheritance factor might not lead to some secondary metabolic difficulty which could be circumvented in time to prevent the onset of deafness.

Prof. NAGER (Zürich) said the bone process in otosclerosis was similar to that in fragilitas ossium, where there was also a defect of the osteoblasts. In otosclerosis there must be an endocrine factor, because the condition usually started at puberty and the symptoms arose only at the moment that the joint was attacked. The process might be present in the capsular part without showing symptoms. Treatment with thyroxine often reduced the tinnitus. Hyperparathyroidism, which bore many similarities to otosclerosis, had been produced by intoxication with certain vitamins.

Mr. F. J. CLEMINSON remarked on the wide distribution in some cases of the otosclerotic changes. The late Dr. Albert Gray had stated that otosclerosis invariably began in, and was for long confined to, the region of the fenestra ovalis.

NEWARK HOSPITAL.—Last year workpeople subscribed the record sum of over £2000 to this institution, but the authorities would like to see the subscription list equal the voluntary levy. The average cost per bed here has been reduced from £101 to £97 12s. 7d., and the length of stay of in-patients from 22 to 20 days.

HUNTERIAN SOCIETY

INTRODUCING a discussion on March 16th at a meeting of this society (Dr. W. BRANDER, the president, being in the chair) on the subject of

Fatigue

Dr. ADOLPHE ABRAHAMS said that among the presenting symptoms for which practitioners were most commonly consulted were tiredness, or one of its equivalents, lack of energy, premature exhaustion, undue fatigue, lassitude. Certain serious pathological states—myasthenia gravis, Addison's disease, malignant disease, Addisonian anæmia, diabetes, tuberculosis, post-influenzal debility—were accompanied by asthenia. But the majority of patients who complained of chronic fatigue were not suffering from any serious or indeed any disease at all, nor as they alleged from over-work; they were simply bored. Yet it was a matter of common experience that the amount of congenial work which even an average person could undertake was colossal. Dr. Abrahams here related a personal experience.

"When I was a house surgeon at St. Bartholomew's," he said, "the practice—whether or no it obtains to-day—was to go on full duty every week-end in five, when from midday Friday until midday Tuesday you were responsible, in addition to your routine duties, for every surgical emergency. I recall one such full duty when through continuous pressure I never completely undressed during the four days and nights. It happened moreover that for most of that week-end there was a dense fog, and as a consequence I lost all distinction between day and night, all conception of time. I experienced a sense not of fatigue but of supreme happiness, the memory of which persists to this day. I recall a similar experience during the war; but it is superfluous to elaborate what everyone here has also encountered: periods of continuous intense work congenial and satisfactory to be contrasted with the sense of exhaustion only too inevitable when the work, though far less exacting, is of a nature which is for one reason or another uninteresting and unprofitable."

We were all agreed, Dr. Abrahams continued, that work as such never caused a breakdown; some mental conflict must be present. Of course when patients came with the story of recent gross reduction in their ability to undertake exertion, physical or mental, it was natural to try to identify some responsible toxin, acting as a brake upon the machinery of activity. We admitted the influence of certain accepted toxins—tuberculosis, malignancy, influenza—but what were we to say of the more elusive toxins in focal sepsis? Once determined to incriminate some such abnormality and having excluded the accessible teeth, tonsils, sinuses, prostate, gall-bladder, appendix, and pelvic organs, there remained the almost unlimited field provided by the alimentary canal. Contemporary advertisements discovered here the invariable cause of tiredness and sought its cure in suitable pabulum or the eradication of intestinal poisons. But both the scientifically minded physician with his toxins and the more matter-of-fact practitioner who accepts the idea of boredom must not forget the psychologist who finds in fatigue a defence against anxiety or the undertaking of responsibility or even Nature's protection against over-exertion.

Dr. Abrahams then turned to the problem of fatigue as an accepted physical consequence of muscular exercise. Fatigue is due to exhaustion of the substances required for the supply of energy or more exactly to the accumulation of sarco-lactic acid, the excess which the blood stream is unable to wash out. If exercise is of such severity that the lactic

acid produced is no more than can be removed simultaneously by oxidation—accepting as the maximum intake of oxygen four litres a minute—fatigue will not occur until other factors of exhaustion enter into the problem. But with really violent exercise the generation of lactic acid is far too considerable for its elimination—e.g., in the case of a sprinter, 1 gramme of lactic acid accumulates for every stride taken, i.e., 40 grammes in the hundred yards. Athletic training to some extent consists in perfecting the circulation for the removal of lactic acid, but it also embodies the education of the muscles to neutralise fatigue products or perhaps to tolerate their presence. The great athlete, Dr. Abrahams thinks, has muscles constitutionally superior in this respect. Perhaps the maximum accumulation of lactic acid possible to the most highly trained individual is 120 grammes. Furthermore the capacity to resist fatigue is bound up with the willingness to push oneself to the last degree; the seat of fatigue is in the nervous system and the available reserve is immeasurable. In long-continued exercise of submaximal severity, fatigue may be due to shortage of fuel. American experiments upon marathon runners had shown an exact correlation between exhaustion and hypoglycæmia which Dr. Abrahams had been unable to confirm. But exhaustion during a substantial athletic effort was a disturbed mechanism concerned with several widely different factors; for in addition to the shortage of fuel, to the accumulation of lactic acid, to the element of monotony, there was the prevention of loss of heat and of moisture under certain unfavourable conditions. The lassitude often experienced on the day or days following a severe effort had been attributed to myocardial weakness and the same explanation had been applied to the incapacity for effort after bacterial illness, especially influenza. "I am unable," he said, "to agree that any direct cardiac association need be invoked. After all, the muscular metabolites must have an effect upon the central nervous system and to this I attribute protracted and delayed fatigue, and, I may add, the symptoms which are on insufficient evidence accepted as 'heart-strain'."

MENTAL FATIGUE

Dr. C. S. MYERS, F.R.S., said that fatigue is usually defined as "that state of lessened activity of an organ which results from its previous activity." But so varied are the effects of prolonged mental work, so complex and so widespread is the "organ" of mind, and so ignorant are we of the nature of mental activity that a correspondingly succinct definition of mental fatigue would fail to serve any useful purpose. On grounds of physiological analogy, we might at first be disposed to attribute mental fatigue to the exhaustion of locally available mental "energy." But the only apparent evidence that we had of such a cause of mental fatigue related to structures outside the central nervous system—namely, in the effects on consciousness produced by stimulating the "protopathic" or "spot" system of sensibility. These effects were easily observable in the skin; where, if any one heat spot or cold spot is re-excited immediately after its previous stimulation, it would fail to elicit a second sensation. Its previous response, comparable perhaps to an explosion, had apparently resulted in complete exhaustion: rest is needed for its recovery. But there were other sensations, if not too intense, which seemed virtually indefatigable. We can listen almost eternally to the gentle ticking of a clock or endure, likewise without apparent sensory fatigue, the

continuous daylight of a northern summer. There are other prolonged but more intense sensations—e.g., the hearing of a continuous loud tone, which, while not suffering appreciable change themselves, nevertheless—owing, it is believed, to central inhibition—result in a rise of the threshold of hearing for tones of the same and of neighbouring pitch. So far as cerebral fatigue is concerned, it might be wondered whether any impairment of mental activity would be expected either through the exhaustion of locally available energy or through the accumulation of toxic influences due to its exercise. Conscious processes however seemed to involve the activity of extensive areas of the brain functioning as a whole; the notion of “centres of consciousness” was fast becoming obsolete.

Uninterrupted concentration at any task, Dr. Myers said, is unnatural; it is our nature to take repeated brief rests during any long period of mental work. But whereas the uninterrupted maintenance of mental activity in one particular field of attention cannot endure for long, the freer play of phantasy in day-dreaming and in sleep seemed untiring. Feelings of mental weariness are not invariably a faithful index of mental impairment; lessened output of mental work may indicate that we are mentally fatigued without our necessarily feeling so, or we may feel mentally fatigued without necessarily showing it in poorer work. Measurement of the output of work was at present our most trustworthy index of mental fatigue, for unfortunately we have no sufficiently reliable objective tests of mental fatigue. Purely physiological tests have proved of little use. Periodically interpolated mental tests are at the mercy of the will and of the feelings of the subject; they are also subject to the effects of practice and of consequent automatism; and they differ, owing to their necessary simplicity, from the more complex directive, aim-seeking characters of higher mental work. There can however be no doubt that, in general, the efficiency of performing certain interpolated mental (e.g., arithmetical) tests is lowered by continuous mental work. Both the feeling of mental fatigue and fatiguability showed vast individual differences. The obsessional type of psychoneurotic might be kept by his abnormally strong perseveration incessantly at work when the normal worker would be unable to resist from taking protective rests. Especially he, but also even the best balanced and most vigorous person, under sufficiently prolonged or intense mental activity would ultimately suffer, sometimes quite suddenly, from pathological fatigue or so-called mental breakdown. Extreme muscular fatigue had never been shown to cause mental breakdown.

Some light was thrown on the pathology of mental breakdown by considering the effects of prolonged activity at the lowest levels of the central nervous system. As the spinal flexion reflex tires under continuous excitation or frequent excitation, it becomes weaker and more tremulous, and may finally even cease altogether. But during this fading there occur brief periods of intermission and even of replacement by the antagonistic response of extension; inhibited movements are more ready to break through. The same occurs when we are at work in some particular field of mental activity. Antagonistic and irrelevant fields of attention are successfully inhibited, at first without voluntary effort owing to the incentive of interest, but later, as interest wanes and boredom enters, through the exercise of volition. Finally as this directive activity of the will fails through fatigue, we can no longer, despite the utmost

effort, attend to the work on which concentration is required. Thus local boredom gives place to general fatigue. Continued cortical stimulation of the flexor area results in a facilitated increasing response, then to a rise in sensitivity of the antagonistic extensor area, and finally to a quasi-epileptiform wave of movement spreading to neighbouring motor areas. These changes were in some aspects analogous to the collapse of the higher coördinating centres and to the wasteful dissipation and short-circuiting of energy, characteristic of mental breakdown through overwork.

It seems, Dr. Myers concluded, that mental fatigue is most evident and serious when the work is of a kind that demands concentration of attention, and that then its most prominent feature is a collapse of “directive activity” which manifests itself in impairment and distraction of attention, loss of skill and deficient effort, in irritability and other symptoms of loss of self-control, and finally in more serious disorders of volition, cognition, and emotion. But in addition to such fatigue of volitional direction, there is likewise a fatigue of the mental processes which are subject to such direction.

But, he added, we do not know what occurs when fatigue sets in. We may conjecture that synaptic resistances are increased, or that adverse chemical bodies are formed, like acetylcholine, neurogenic and humoral in nature, or resembling in their action the toxins generated by excessive muscular activity. It may also be that antitoxins can be formed, resistant to such fatigue. But we are as ignorant of these as we are ignorant of the supposed toxins and antitoxins responsible for, or defensive against, sleep. We are also ignorant of the differences which are likely between the fatigue caused by intensive or prolonged mental work and the fatigue caused by deprivation of sleep.

FATIGUE IN INDUSTRY

Dr. J. C. BRIDGE said that in his visits to centres of industry he had been impressed by the ability of workers to continue at heavy tasks for eight or more hours every day of the working week; he felt sure that part of the explanation lay in the fact that the work was not actually continuous, but the men had “breathers,” intervals of rest between the tasks. Mechanisation too in recent years had done much to reduce the muscular energy necessary at many of the heavier kinds of work. He assumed there was a physiological fatigue which was good, and healthy, but he knew of no means of determining subjectively where this ended and pathological fatigue began. A recent move was to substitute for three eight-hourly shifts four six-hourly ones; one result of that change had been to increase the output. Repetitive work in attending to machines of uncanny complexity must produce in the worker a sense of boredom or fatigue. In making clothing the component articles were sent along on a continuous band; workers along its path had a set piece of work to finish before the garment was passed on to the next. That kind of monotony was well calculated to produce fatigue. When intervals of rest were allowed, many of the women occupied themselves with knitting! He could only presume that no more than a small part of the human anatomy became fatigued by the work. Fatigue in industry had been for some time diminishing, and was still being reduced, but its form varied owing to the changing forms of employment. Study of these was important.

DISCUSSION

Dr. GUY P. CROWDEN found it impossible to regard fatigue as a single entity; he found himself unable to isolate it from what appeared to be the daily cycle of every active person. The problem to be faced was: is the phase of recovery a real and full compensation for the expenditure of energy? At the end of a day, and at the end of the week, fatigue had overtaken recovery and—speaking from the physiological standpoint—there was some leeway to be made up. Did the routine of life permit the day-to-day equilibration of that cycle? One could not assume a dominating influence preventing equilibration apart from many factors known to influence fatigue and recovery. In the case of the worker distinction must be made between dynamic fatigue as a result of movement efforts, and static in which there was fixed attention with possible strain. There was too the factor of environment. Some work was done in comfort; ventilation, humidity, air movement, and radiant heat were important, as well as distractions due to noise or vibration, not forgetting air pressure (caisson work). In all this it was impossible to ignore the personal factor; much depended on whether the person concerned was educated and able to appreciate the significance of changes in routine, the regulation of light, and even the wearing of protective garments. Some single and apparently trivial factor might turn out to be the chief cause. A person engaged at a desk might be at work which involved postural strain, and he might suffer considerable fatigue in local muscle groups. Fatigue meant a diminution of capacity as assessed by the previous optimum of physical fitness. A further factor of real importance was that of appropriate and sufficient food, linked up with congenial home conditions.

Dr. R. K. HOWAT argued that the process of recovery from fatigue was never complete. It was true that after a period of rest one might feel as fresh as ever, but that did not mean complete recovery. Every living creature entered on life with a definite reserve of energy, and even with sufficient food and periods of rest there was a danger of being on the wrong side in the matter of equilibration. Fatigue might be a protective agency against complete exhaustion.

Dr. STEWART WEBB regarded fatigue as largely individual; many were content to perform the most monotonous tasks so long as they were not called on to bear any responsibility.

Dr. H. L. ATTWATER spoke of the delicate and exacting work involved in making filament lamps, the suspension of the filament occupying about ten seconds each. Monotony was countered by the offer of bonuses to those who dealt with the largest number of lamps each week, and there were no complaints of fatigue. On the other hand, those who had to produce dies for very fine work only put in short hours and did suffer from fatigue.

Mr. HOPE CARLTON agreed that fatigue was largely central, and the question of shock was important. A boxer who had been knocked out was suffering from fatigue, and that was a central lesion. Discipline also had much to say. During the late war the endurance of a trained battalion as compared with that of new recruits was largely a question of superior discipline. Recent work at Down Farm on fatigue in smooth muscle had disposed of old ideas on the subject; there was no deficiency of blood chlorides, even up to the point of death. Fatigue was not due to histamine bodies; the death-dealing substance lay in the cell.

Dr. LETITIA FAIRFIELD insisted on the importance of rhythm, which became evident on watching the methods which workers chose for themselves. Children's favourite method of doing things was to attack them in bursts of energy, alternated with periods of rest, and if allowed to carry on as they pleased they were quite fresh at the end of a long day; whereas if a certain procedure was imposed on them they soon tired of the task. When a person's whole desire and interest was concentrated on his work, this had the effect of postponing and diminishing the amount of fatigue. Men working at exacting occupations for long hours during the late war would not confess to fatigue although their muscles were twitching and they were evidently spent. Absence of mental conflict was very important.

Dr. ABRAHAMS in replying said it was usually the fussy person who was particular about the athlete's diet; the great athletes did not bother about it. Also, the record-breaker was not usually the educated person; if he were he would commence to reason while at his running, and the first question he would ask would be, "Why am I doing it? Is it worth while?"

LIVERPOOL MEDICAL INSTITUTION

A MEETING of this institution on Feb. 27th, with Mr. G. C. E. SIMPSON, the president, in the chair, was devoted to short papers on problems in general practice.

Treatment of Psoriasis

Dr. R. M. B. MACKENNA said that certain definite precautions should be taken by persons prone to psoriasis; they should not wear tight clothing, they should avoid alcohol, foods containing spices, and fatty foods, and as a rule they should expose themselves to sunlight as much as possible. With a severe attack in the stage of efflorescence, an expectant line of treatment should be adopted; rest in bed was a measure which was usually omitted but often did more good than any other.

In the discussion which followed, Dr. F. GLYN-HUGHES, in reference to Dr. MacKenna's mention of German work supporting the idea of faulty fat metabolism in psoriasis, said that until two months ago it had been his practice in Belmont-road Skin Hospital to put all his psoriasis patients on a fat-free diet. He was satisfied that this had decreased the time required to clear the skin. Lately he had gone further and put these patients on a milk diet only, and had been very pleased with the result, particularly in very chronic cases. The method had the advantage that it could be carried out at home. Speaking of the use of intramuscular injections of mercury, he said he would like to be sure that their good results were due to the action of the drug on the disease proper, and not to its action on syphilis, which could produce lesions closely resembling those of psoriasis. The Wassermann reaction in these cases was not always reliable.

Dr. G. S. SWAN said that psoriasis was one of the bugbears of a general practitioner's life. His main object was a form of treatment to enable the patient to continue his employment. Baths twice daily, followed by complete inunction, were almost impossible of achievement outside hospital.

Phlyctenular Conjunctivitis

Mr. A. MCKIE REID, in a paper on the aetiology and treatment of phlyctenular conjunctivitis, began

by pointing out its association with cervical adenitis, pathological tonsils and adenoids, occasional bone and joint disease, and with hilar and abdominal tubercle. The lesion showed neither tubercle bacilli, true giant-cells, nor caseation, and the evidence in favour of its being tuberculous was chiefly clinical and experimental. The occurrence of phlyctenules when sacs of tubercle bacilli were tied in the body of non-tuberculous animals, when external irritants (e.g., staphylococcal toxin) were introduced into the conjunctival sac of tuberculous animals, as a focal reaction after a skin-test and as a local reaction after a conjunctival test for tuberculosis, were quoted in support of the theory that the disease is a focal manifestation of systemic disease—a tuberculo-toxic manifestation in the allergised ocular epithelium. Treatment included local application of unglyhydrarg. oxid. flav. and treatment of the accompanying catarrhal conjunctivitis with saline lavage and 2 per cent. mercurochrome drops (zinc and silver salts were contra-indicated). Improved hygiene, administration of vitamins, hyperalimentation, artificial sunlight, and, where systemic tuberculosis was present, institutional treatment were useful. The disease was much commoner in communities where economic and industrial conditions were bad, and Mr. Reid maintained that its prevention was essentially a sociological problem.

Dangers of Nose-blowing

Mr. JOHN ROBERTS said that the act of nose-blowing, although accepted as a necessary civilised convention, was not physiological, because normally the nasal secretions (with their entangled bacteria and dust) pass backwards into the pharynx and are swallowed. It seemed probable that the body, in this singular way, kept vaccinating itself against prevalent micro-organisms through the agency of the stomach and intestinal canal. By a consideration of the aerodynamics of the middle-ear cul-de-sac it could be clearly shown that the forced passage of air through a constricted nasal passage could easily impel some secretion (on its way past the orifice of the Eustachian tube) into the tympanic cavity—particularly if the tympanic membrane was absent or perforated. Clinical experience had conclusively shown the liability to acute otitis media following injudicious and forcible nose-blowing in such conditions as the common cold, measles, and scarlet fever, and also in swimmers and divers.

In the discussion, Mr. MCKIE REID said that vigorous nose-blowing immediately after excision of the lacrymal sac was sometimes followed by an alarming swelling of the eyelids suggesting cellulitis. This was surgical emphysema due to the tissue planes in the eyelids, laid open by the incision, being brought into direct communication with the intranasal cavity. The condition resolved quickly on the application of pressure-pads and abstention, [for a day or two, from nose-blowing.

Dr. W. B. BENNETT said that he considered the safest method was to "blow" each side of the nose separately, somewhat after the practice of the manual labourer, who closed one nostril with his finger, while he cleared the other, which remained open. A handkerchief could, of course, be held near the nose.

Dr. R. J. MARTIN said that blowing the nose was an expiratory movement resulting from irritation of the nasal mucous membrane. While normal ciliary action propelled debris downwards, to be disposed of by the acid gastric juice, this mechanism often needed assistance during modern conditions of town life. This assistance was provided by the acts of

sneezing, coughing, and blowing the nose. The danger of forcible nose-blowing arose when infected mucus lay at the entrance to the Eustachian tube, and infection of the middle-ear cleft was particularly likely to occur in those cases in which a dry perforation already existed in the tympanic membrane.

Mr. H. V. FORSTER read a paper on Tonsil Function and the Attitude to Tonsillectomy, and Mr. H. C. W. NUTTALL one on Septic Fingers.

ROYAL ACADEMY OF MEDICINE IN IRELAND

A MEETING of the section of obstetrics and gynæcology was held on Feb. 14th with Dr. J. F. CUNNINGHAM, the president, in the chair.

Sudden Death During Labour

THE PRESIDENT showed a specimen from a patient in whom a cardiac lesion caused death during labour.

The patient, a primipara aged 33, appeared to be quite normal when she came into hospital. Her lungs and heart were examined and nothing abnormal was found. There was no albumin in the urine. After she had been in labour for 12 hours it was thought that she was in the second stage. No vaginal examination was made. After she had been 15 hours in labour the head appeared on the vulva. The patient said that she could not see at all, her eyelids got very swollen and she became cyanosed. She was given chloroform and had a very easy low forceps delivery. She was given chloroform for only seven minutes. She died suddenly, and the baby was stillborn. Forceps were used because the patient was in great distress owing to the cyanosis. At post-mortem examination the abdominal organs and the brain were found to be normal. The lungs showed adhesions and evidence of old-standing pleurisy. There was moderate fatty infiltration of the heart, but the valves were normal. There was no evidence of endocarditis. The right ventricle was dilated, and the wall was extremely thin. There was an antemortem clot in the left ventricle.

Dr. Cunningham said he had previously seen two cases in which a clot had appeared, but it was in the right auricle or ventricle. This was the first time he had seen a clot in the left ventricle.

Dr. BETHEL SOLOMONS said that sudden death in labour had been attributed to various causes. "Labour shock" as a diagnosis usually meant ignorance of cause of death. Embolus, postpartum hæmorrhage, acute cardiac dilatation, and many other factors were blamed. In this case it was impossible to exclude chloroform as the cause. He still believed that chloroform was dangerous in hospital practice, whereas it was apparently safe in the hands of an experienced practitioner. The post-mortem specimen which had been shown did not solve the puzzle.

Dr. G. C. DOCKERAY said that the specimen reminded him of one in the College of Surgeons in which a large ball thrombus in one of the chambers of the heart had caused death. It was a good deal larger than the clot in this case, but presumably the mechanism was the same in both. Most chloroform fatalities seemed to occur in patients with perfectly normal hearts; so selection of patients for chloroform would probably make little difference. Many cases of so-called acute dilatation of the heart were really cases of tachycardia with, in addition, fibrillation.

Dr. F. DOYLE said that this was a case which would fill many people with alarm. There was nothing which could clinically suggest death, and it was very remarkable that death should have been so sudden.

Death might have been due to the anæsthetic, but apparently this was not so. Nitrous oxide and oxygen was in his opinion the proper anæsthetic for these cases. It would be interesting to know whether in this case the chloroform had really had any effect on the heart or not.

Dr. KERRY REDDIN said that in the last two months he had known of three patients with congenital heart disease who had been sent out of maternity hospitals undiagnosed. He thought there was great slackness in examining the hearts of the women and the babies in the maternity hospitals, and said that neither heart cases nor tuberculous cases were properly examined there.

The PRESIDENT, in replying, said that the absence of any clinical symptoms when the patient came into hospital first could be explained by the pathological report which said that she had no valvular lesion of the heart at all. When she became distressed and blue during labour it was very difficult to know the reason. He did not think that the anæsthetic had had anything at all to do with the death of the woman, and believed the cause of death must have been that the heart went through a great strain during labour; this strain increased towards the end of labour, and it was then that the anæsthetic was given. This death had not altered their routine in the hospital of giving chloroform. Every case on admission was examined to see if there was any heart lesion, and if there was, this was taken into consideration when an anæsthetic was being given.

Ovarian and Endometrial Graft

Dr. BETHEL SOLOMONS reported a case in which an ovary and a piece of functioning endometrium from the uterus were grafted from one woman to another. He knew of no similar recorded case. The patient had previously had years of amenorrhœa and much hormonal treatment had failed; but menstruation followed the operation.

The PRESIDENT said that this was probably the first time that an operation such as was described by Dr. Solomons had ever been performed. It was extremely interesting to hear of a graft of ovary and of endometrium being made at the same time. He thought it was common to find that a graft of an ovary into the rectus muscle failed. The ovary did not live very long. The graft often gave rise to pain, and later a cystic swelling sometimes appeared in the rectus muscle. It was noteworthy that the endometrium had an effect on the ovary as well as the ovary on the endometrium. He thought that very likely the endometrium was a ductless gland, and would have this effect. He wondered if it was the patient's own ovary which was now functioning, in which case the result would be likely to be more permanent. The patient's own ovary might have been stimulated by the operation; this would have an effect on the endometrium; and the endometrium in turn reacted on the ovary. It was fairly easy to graft endometrial tissue, but very difficult to graft ovarian tissue.

Dr. T. M. HEALY hoped that Dr. Solomons would report later on on the behaviour of the endometrium. It would be interesting to know the degree by which the uterus was covered with endometrium in six or eight months' time, and whether it was behaving as normal endometrium did in the ordinary individual. Dr. A. W. SPAIN and Dr. DOCKERAY spoke of the relation of blood groups to success in grafting.

Dr. SOLOMONS, in reply, said he thought a graft lasted for two or three years. He believed that the

menstruation, which had already occurred several times, was due to the presence of the grafted ovary and the endometrium.

Juvenile Rheumatism

Dr. C. J. MCSWEENEY addressed the Section of State Medicine on this subject at a meeting held on Feb. 28th with Dr. J. A. HARBISON, the president, in the chair. He began by saying that he thought rheumatism responsible directly or indirectly for 1500 deaths a year in the Irish Free State. His impression was that the disease was at least as common in Dublin as it was in the larger cities in England. It was essential to recognise that nowadays rheumatic manifestations in childhood were usually subacute, and even subclinical; hence the replacement of the term "acute" by the more precise "juvenile." Subacute rheumatism was more likely to lead to cardiac involvement because it was more often neglected. Where no special provision was made for rheumatic children not less than 60 per cent. of them developed organic heart disease, and any scheme aiming at the prevention of heart disease must provide for the ascertainment of rheumatic children at an early stage. Probably not more than 10 per cent. of cases under supervision would require hospitalisation at any one time, but supervision of all rheumatic children should be maintained at intervals of three months for the whole of school life. Control of the disease was largely a question of ensuring a correct régime of rest, sleep, diet, and clothing. In selecting suitable cases for hospital, and in assessing the activity of the rheumatic process, estimation of the sedimentation-rate of the red cells was of great value. Summarising the results obtained in the treatment of 598 cases in a special hospital in Cardiff between April, 1929, and June, 1934, Dr. McSweeney said that of 492 children admitted with early carditis 376 had normal hearts on discharge after an average of 10-12 weeks' treatment. The relapse-rate was also less in children who had had hospital treatment.

Dr. W. R. F. COLLIS said that the attitude of the average clinical teacher towards rheumatic fever was apt to be depressing, but Dr. McSweeney's results with cases detected early were exceedingly promising. He deprecated incomplete removal of tonsils, which did more harm than good to rheumatic children.—Dr. KERRY REDDIN complained that little interest was evinced by the children's hospitals in rheumatic children.—Dr. R. E. STEEN described juvenile rheumatism as a disease of malnutrition and faulty hygiene, and said that adequate rest was impossible in the patient's own home.—Dr. DOROTHY PRICE held that rheumatic children could not be properly handled in an out-patient department.—Dr. T. T. O'FARRELL thought the problem was one for parents, school teachers, and public health authorities rather than clinicians.—Dr. E. HARVEY emphasised the need for research into causation.—The PRESIDENT said the detection of 30 rheumatic cases a week in the course of school medical inspection in his area showed how serious was this problem in Dublin. Specific provision was necessary for these cases.

Dr. MCSWEENEY, in reply, said that absolute rest in bed constituted 95 per cent. of the treatment of juvenile rheumatism. Severe cases of chorea become quickly quiescent with no other treatment than absolute immobilisation. A pulse-rate persistently over 90 during sleep in a rheumatic child was suggestive of activity. Relapses sometimes occurred during hospital treatment, but were uncommon.

REVIEWS AND NOTICES OF BOOKS

La tuberculose ostéo-articulaire

Evolution—Diagnostic de début et Traitement.
By Dr. JACQUES CALVÉ (de Berck), with the
collaboration of M. GALLAND and M. MOZER.
Paris: Masson et Cie. 1935. Pp. 208. Fr.50.

TUBERCULOSIS in any part of the body generally calls for prolonged treatment and even more prolonged observation of the patient after discharge from hospital; and this is particularly true when bones and joints are involved. It is therefore to be expected that the best teaching on the treatment of tuberculous joints should come from surgeons who have had many years' experience in a hospital chiefly devoted to the treatment of these conditions. Dr. Jacques Calvé and his splendid hospital at Berck enjoy a reputation extending far beyond the borders of France; this work is therefore sure of an international welcome. It is written for those who are already familiar with the ordinary manifestations of tuberculous joint disease; the absence of text-book descriptions is a refreshing feature in a book which gives an informal presentation of the author's views on the whole subject, with special reference to the three most common sites of infection—the spine, the hip, and the knee. The views of other workers are discussed with frankness and keen insight and in a generous spirit.

The old-fashioned "surgical" conception of a tuberculous joint is shown to be wrong. It is not the case of a tuberculous joint occurring in an otherwise healthy individual, but of a tuberculous patient who happens to have a focus of disease in a joint. Adequate general treatment is the first essential. Under favourable conditions the lesion runs its course with a regularity not unlike that found in scarlet fever or pneumonia, the difference being that the process is very much slower. There is a stage of invasion; then a long battle between the local disease and the body's defences, marked by attack and retreat on one side or the other; in the end the victory generally falls to the patient and repair begins. The profession in this country now recognises that so-called conservative measures are the most important feature in the successful treatment of tuberculous joints; yet there is still an impression that these measures have merely been tried empirically and found to be good. Calvé shows *why* conservative treatment is rational and therefore correct. In the absence of a specific remedy of proven value, the surgeon serves his patient best by placing him in a suitable environment and putting the damaged joint completely at rest until the lesion becomes quiescent. At this stage operative fixation is often of value in stabilising a joint that has been disorganised by disease. There is also an indication for early operation—i.e., when an early tuberculous focus appears in the neighbourhood of a joint. Prompt eradication of the focus may save the joint from involvement. But, generally speaking, operative treatment is no more than an occasional accessory.

On one major point we are inclined to disagree with Dr. Calvé. He does not advocate exploratory arthrotomy in early cases undertaken to settle the diagnosis. In the knee, at any rate, this simple and safe operation will often give the correct diagnosis when the test of function leaves the surgeon in doubt. Biopsy is not infallible but it is the most certain means of diagnosis at present known in doubtful cases of arthritis of the knee and ankle.

The early arthrodesis of every tuberculous joint, as advocated by Hibbs, makes an immediate appeal to everyone familiar with the laborious technique and the constant attention to detail demanded by the conservative régime, and there is a tendency for some surgeons to accept Hibbs's teaching without weighing the possible cons against the alluring pros. The older orthopædic surgeons in this country have learned their lesson, though little has been said by them in the literature. Junior men, impatient of conservatism, should read Calvé's splendid discussion of this problem; it will cause them to make haste slowly.

There are few things in this delightful book that call for adverse comment. The section on differential diagnosis is too short to be of much value and is probably unnecessary; and there is no excuse for printing X rays of the spine upside down—see pp. 78 (Fig. 24—right) and 81.

Post Mortems and Morbid Anatomy

Third edition. By THEODORE SHENNAN, M.D.,
F.R.C.S. Edin., Professor of Pathology in the
University of Aberdeen. London: Edward
Arnold and Co. 1935. Pp. 716. 30s.

THIS book has long been the standard work in English devoted solely to post-mortem technique and morbid appearances. It is essentially a practical work and gives the reader precise and helpful information obviously based on the author's own extensive experience; innumerable hints on minor points which may seem obvious to the morbid anatomist will be of considerable help to the student. For the most part the book is limited to pure morbid anatomy, but morbid histology and general pathology have been included where they are necessary for a proper appreciation or interpretation of the post-mortem findings. This is particularly true of the section on renal disease in which the author has not hesitated to include even the clinical picture.

The new edition retains the general style and lay-out of its predecessors and is arranged as far as possible in the order in which the organs are examined according to the author's technique. A number of sections have been rewritten, in particular those on endocarditis, tubercle, and splenic and renal disease. There have also been several lesser alterations, and new illustrations have been added. The section on disease of the coronary arteries might well have been enlarged, particularly the part describing the appearances of old and recent thromboses. There is a minor printer's error on p. 438.

The new edition, like its predecessors, will certainly prove useful if not indispensable to anyone called upon to perform post-mortems.

Human Pathology

Fourth edition. By HOWARD T. KARSNER, M.D.,
Professor of Pathology, Western Reserve University,
Cleveland, Ohio. London: J. B. Lippincott
Company. 1935. Pp. 1013. 45s.

THE major alterations in this edition have been made in the chapters on tumours, the hæmopoietic system, the endocrine diseases, and the central nervous system. Apart from these, a number of lesser changes appear in the text, and all the important advances

made since the last edition appeared in 1931 are noticed. The new material has been carefully sifted and nothing included which is not likely to find general acceptance. The section on the anæmias is unduly brief and in discussing tubercle insufficient stress is laid on the importance of primary infection. The lists of references also call for criticism in a text-book designed for students. They are very long and unusually complete, but no undergraduate could judge of the relative importance of the papers mentioned without some help.

The book as a whole is remarkably complete without being unduly large and the teaching is sound. The photographs and drawings are well chosen and reproduced.

Infant Behaviour, Genesis and Growth

By ARNOLD GESELL, Ph.D., M.D., Sc.D., Director of the Clinic of Child Development and Professor of Child Hygiene in Yale University; and HELEN THOMPSON, Ph.D., Research Associate in Biometry, the Yale Clinic of Child Development. London: McGraw Hill Publishing Company, Ltd. Pp. 343. 18s.

Dr. Gesell is known for his comprehensive objective studies of infant behaviour. The present volume is based upon his earlier work; it deals with genetic interpretations and methods of investigation, both by cinematographic observation and actual daily tests upon the growing infant. There is scarcely a muscular movement of the human infant from birth to the second year which has not been carefully studied from day to day in order to investigate growth in coördination and the emergence of intelligent social behaviour. The book contains a series of graded estimates of the child's ability to carry out simple operations. Each test situation has been studied with the energy of Hercules.

No student of infancy can be without this important book. It should be of value to all those who are interested in the academic study of infant behaviour and also and particularly to those who find it so difficult to decide whether mental retardation has appeared in the early months of life. We must congratulate the authors in having produced in such an excellent form the results of their far-reaching researches.

An Index of Differential Diagnosis of Main Symptoms

Fifth edition. By Various Writers. Edited by HERBERT FRENCH, C.V.O., C.B.E., M.D. Oxon., F.R.C.P. Lond., Consulting Physician to Guy's Hospital; late Physician to H.M. Household. Bristol: John Wright and Sons Ltd.; London: Simpkin Marshall Ltd. 1936. Pp. 1145. 63s.

THE new edition of this important book reflects great credit on Dr. French and his 18 collaborators. Two new authors, Dr. Bruce Perry and Mr. W. H. Ogilvie take the places of the late Dr. Carey Coombs and Mr. R. P. Rowlands. Dr. Perry has contributed articles on angina pectoris, cardiac bruits, and irregular pulse; Mr. Ogilvie on club-foot, spinal curvature, and inguinal swellings. Descriptions of new diagnostic tests of proved reliability, such as the Aschheim-Zondek, have been introduced and this new edition attempts as before to cover the whole diagnostic field of general medicine, surgery, gynaecology, dermatology, neurology, and ophthalmology. Certain

diseases which have recently become less unfamiliar, such as botulism, abortus fever, Pink disease, and tularæmia, receive attention. The statement, already inaccurate, that the organism of psittacosis is unknown, shows how difficult it is to keep a work of this size up to date. Dr. Hurst's otherwise admirable article on constipation, which should be read alike by doctor and medically minded layman, offers certain points in the differential diagnosis between acute constipation and acute intestinal obstruction, which may not be universally acceptable. He states that "visible and palpable peristalsis is never present except in obstruction," whereas, in fact, it is often to be observed in healthy persons of lean habit. He says, moreover, that vomiting is never fæculent in non-obstructive cases except "at a very late stage," but is not this equally true of obstructive cases? No experienced clinician would wait for fæcal vomiting before diagnosing acute intestinal obstruction. On the other hand, Dr. Hurst wisely emphasises the importance of early diagnosis of absolute constipation, if necessary, by giving two enemata at short intervals.

Dr. French, not only the editor but also the most prolific writer of the book, has himself supplied nearly 150 articles on a great variety of subjects. There are many excellent photographs and coloured plates, those of the fundus oculi illustrating Mr. H. L. Eason's notes on ophthalmoscopic appearances being worthy of special mention.

From a Colonial Governor's Notebook

By SIR REGINALD ST.-JOHNSTON, K.C.M.G. London: Hutchinson and Co. (Publishers), Ltd. 1936. Pp. 285. 12s. 6d.

Sir Reginald St.-Johnston, barrister, doctor, and administrator, has in this book recounted certain of the experiences undergone, and for the most part enjoyed, during 30 years in the Colonial Service. The book does not attempt to be a chronological record of the author's life in the Colonies, but is, as he says himself, "a series of odds and ends taken from my notebooks during the time I was administering the government of several colonies or dependencies." After qualifying in medicine and being called to the Bar from the Middle Temple, Sir Reginald joined the Colonial Service, and for a period held various judicial and administrative appointments in Fiji. The war intervened, and he saw service abroad and subsequently was attached to the War Office for special duty. In 1920 he was appointed acting governor of the Falkland Islands and later, in succession, colonial secretary to the Leeward Islands, administrator of St. Kitt's and Nevis, and governor of the Leeward Islands, from which post he recently retired.

In describing the official and social duties and responsibilities which fell upon him in the various important posts, the author produces an eminently readable book. Previous works from his pen have led us to expect him to display an eye for coloured environment, dramatic instinct, and a faculty of fluent narrative; here the many entertaining stories which he tells show intimate acquaintance with all aspects of life in the West Indies, in high official circles, and in the lowliest native life. The book abounds with thumbnail sketches of well-known personalities and picturesque descriptions of places, with notes on the natural history and the climatic conditions.

THE LANCET

LONDON: SATURDAY, MARCH 21, 1936

ON FEELING SECURE

THE issue of the crisis through which we have been passing this week will be mainly determined by the workings of the group mind. It may be well to consider how far the national and international reactions of the moment which perplex the politician may resemble the individual reactions observed by the psychiatrist and becoming increasingly familiar to the medical profession as a whole. In times of crisis everyone is deeply concerned with the question of security, and seeks by all possible means to regain the state of calm. Calm, both in the individual and in society, is usually regarded as the normal state and crisis as a disturbance coming from without. A little reflection leads to a different conclusion, for most people and most communities are far less stable than they imagine themselves to be. When we are at peace, we dread more than anything the pain of examining our instability; only in time of crisis do we feel impelled to "get something done." The tendency to avoid facing something that is dreaded is familiar to every member of the profession but is the special study of the clinical psychologists. They distinguish two types of fear, objective and subjective, according to whether the source of apprehension is known to the victim or not. A good instance of the latter is fear of the dark: a person attributes ("projects" is the technical term) to his environment terrifying impulses which exist within his own mind without his being aware of them; he is afraid unless he can have the assurance of his senses that his surroundings are not harmful. The same process of projection is at work when a person (or a nation) suddenly selects a particular enemy and attributes his troubles to that enemy. A patient who feels that he is encircled by enemies is a difficult case to handle. By attributing aggression to others he can regard himself as an exceptionally pacific person, but his own aggressive attitude may rouse such fear in others that they adopt counter-measures—and then his delusion is, of course, turned into reality. This much is old knowledge; more recent researches throw some light on the causes of another type of mentality. There are people who "revel in danger." When others are

with good grounds afraid, they feel calm and to their surprise are strangely at ease with themselves; prolonged peace (they call it "inaction") leads to uneasiness, they suffer from "peace-neurosis" which is "cured" by war. Investigation shows that danger is welcomed because, when the source of mental tension is external as in war, the mind is relieved of an internal strain—that of dealing with its own aggressive tendencies.

The nucleus of the whole problem lies in the mode of dealing with aggressive impulses. If these are coupled with a pleasure in constructive activities, the result is productive work; an example of this may be seen in the gigantic undertakings in Russia to-day. If the individual cannot find satisfaction in constructive activity, for instance if he is unemployed or is put to an ungenial occupation, the necessary condition for the binding of the aggressive impulse to cultural ends is lacking, and there is risk of a breakdown of social relations. The political analogy is revolution, if the aggression is kept within the frontiers, or war if the aggression is projected outwards. This is the reason why in the case of an individual faced with an impending crisis it is so important that his energies should to the last moment be given a constructive outlet. Perhaps the same applies to nations. Recent investigations into the psychological problems of neurotic breakdown and of criminality have disclosed a surprising fact—viz., that the projection of aggression outwards is not simply to preserve the illusion that the subject is a thoroughly peaceable person; it also serves in the mind of the subject an unconscious purpose of preserving a loved object or ideal from hostile attack. This is a complicated concept, but it has the support of the clinical observation that the most effective way of maintaining contact with an aggressive or deluded patient is to show an understanding of his ideals and hidden aspirations and a realisation that behind the barrage of his attacks there is also a wish for good relations. An appreciation of his constructive contributions to society, however slight in fact these may be, goes some way to strengthen the forces of cohesion and pacification within the personality. But such measures may fail, and a resort to force may be necessary. Here clinical experience again helps us; the return to sanity is hastened if the patient is not treated as an outcast. The day when the insane were loaded with chains is over; nowadays contact is not lost even though the patient is forcibly restrained.

In a world where unrest and danger abound it sounds a mockery to speak of feeling secure, but a step in that direction is taken when we can recognise our own aggressive impulses and not blindly project them on to others; we then see our neighbours more clearly and do not confuse their intentions with our own, our own with theirs. Objectivity does not give security, but it enables the darkness to be faced without morbid dread.

ACUTE ASEPTIC MENINGITIS

RECENT work suggests that the "acute aseptic meningitis" of WALLGREN and of GÜNTHER is a true clinical entity, and that its cause is a virus isolated by ARMSTRONG. The disease has come into prominence during the last few years, partly because it is mildly epidemic and seems to be getting commoner, and partly because of its importance in the differential diagnosis of tuberculous meningitis. By the bedside it is often impossible to distinguish these two conditions; yet in one the prognosis is excellent, in the other almost hopeless. Since the description of this new disease physicians have come to recognise that every patient with supposed "tuberculous meningitis" has a possible chance of complete recovery, so long as the chloride content of the cerebro-spinal fluid remains above 650 mg. per 100 c.c., and tubercle bacilli have not been demonstrated. This chance is small, but it does nevertheless exist, and no wise practitioner would willingly conceal it from anxious relatives.

The nomenclature of the whole subject is confusing. Many diseases of the nervous system show a lymphocytic meningeal reaction (e.g., tuberculous and syphilitic meningitis, poliomyelitis, encephalitis lethargica, herpes zoster, and the encephalomyelitis of acute exanthemata); so that the recognition of lymphocytes in the cerebro-spinal fluid does not carry us very far. In making a diagnosis of acute aseptic meningitis the following points will be found of value. The patient may be a child or an adult, and the onset is acute, sometimes preceded by a sore-throat. Severe headache is usually the first symptom and this is soon followed by other evidence of meningeal irritation or of increased intracranial pressure: stiffness and pain in the neck, back, abdomen, or limbs; vomiting; photophobia; restlessness and insomnia. Drowsiness, delirium, or stupor are rare; and convulsions uncommon except in infants. Pyrexia is usual; it is often mild, but may perhaps be high at the onset. Constipation or retention of urine may sometimes cause trouble. In the early stages examination reveals little apart from the usual signs of meningeal irritation, the patient lying on one side complaining of severe headache and refusing to be disturbed. Children may appear very ill indeed, and when they are brought to hospital their parents often believe them to be dying. In infants the anterior fontanelle may bulge. Gross papilloedema, pupillary changes, and cranial nerve palsies do not often develop. Kernig's and Brudzinski's signs are usually positive. Early pyramidal signs in the arms, trunk, or legs may perhaps be found, but these are not conspicuous. Lumbar puncture reveals a cerebro-spinal fluid under increased pressure, clear or slightly cloudy, rarely forming a thin clot on standing. Its cells are increased, usually numbering about 100-300, but sometimes as few as 50 and sometimes as many as 3000. At the onset these

cells may be almost entirely polymorphonuclears; in the course of a few days they are replaced by lymphocytes, and by the end of a week there may be lymphocytes alone. Cultures are sterile; no organisms can be seen in stained films, and guinea-pig inoculations give no result. The prognosis is excellent. For a while pyrexia may be continuous or remittent, but between the fourth and fourteenth days the temperature usually falls by lysis. Recovery is then rapid and most patients are able to leave their beds in the third or fourth week of the disease.

In 1934 ARMSTRONG and LILLIE isolated a new filtrable virus, which caused a lymphocytic meningitis in monkeys and mice. They suggested that acute aseptic meningitis was the disease, in man, which most closely resembled that produced experimentally in animals by their virus, and soon it was found that convalescent serum from patients who had had this particular disease protected monkeys and mice from the effects of the virus. In other laboratories similar strains of virus were isolated, both from patients and from mice, and ARMSTRONG was able to prove that these different types were pathologically and immunologically identical. All this work was done in America, but its continuation in this country is recorded in our present issue where Drs. FUNDLAY, ALCOCK, and STERN report the isolation of viruses, resembling ARMSTRONG'S, from two cases of lymphocytic meningitis of obscure clinical type. The blood-serum of both patients contained antibodies which protected animals, not only against these two viruses, but also against the American strain and against one found in apparently healthy English mice. In brief, it seems justifiable from the evidence now before us to conclude that there is a virus living in some strains of healthy mice, on both sides of the Atlantic, which is capable of producing severe neurological disease in other mice, in monkeys, guinea-pigs, and rats; and that this virus can be isolated from the cerebro-spinal fluid of human patients suffering not only from the well-recognised clinical entity "acute aseptic meningitis," but also from another, more obscure, pyrexial nervous disease. This relation of human illness to virus infection in mice will not escape notice and may prove important. At least we may be sure that the work so far done will be the basis of much further study of the nervous diseases of virus aetiology.

ROYAL MEDICAL BENEVOLENT FUND

THE annual meeting of the Royal Medical Benevolent Fund, to be held on Tuesday next, is a centenary occasion, and its significance should not be lost on us. The Fund represents an organised attempt carried on through 100 years to minister to the needs of the less fortunate of the medical profession through the subscriptions and donations of members of their own calling who are better endowed with worldly possessions. That sounds fine, but as we have had occasion to remark almost annually, the circumstances are not such as to

afford reason for much complacency. For although the Fund has had a long life, and although the energy of the authorities of the Fund has been unremitting and excellently directed, the response of the medical profession has not been proportional; it does not point to a recognition of a general responsibility among us towards our more needy brethren, although the evidence of those needs is convincing and tragic.

Now, on a more cheerful note. There will have been observed by all who consider the well-being of the whole profession—which ought to mean every man and woman whose name is on the Medical Register—that the Fund has lately taken a greater hold on the attention of practitioners. For the last three years, when reviewing the annual report, we have been able to announce a stronger condition of the Fund and the report for the year ending Dec. 31st, 1934, showed real progress in an increase of income, an increase in the number of annual subscribers, and an increase in small donations to the special Christmas Fund. Annual progress of this sort is highly satisfactory, and will have given great encouragement to the authorities of the Fund; none the less if the progress were maintained at the same rate it would still take some 50 years before the aggregate benevolence of the medical profession towards its less fortunate members would reach the annual sum needed to deal with the sad cases which come before the Fund for assistance. The stories published by the committee of the Fund from time to time in the columns of the *British Medical Journal* and *The Lancet* show that there exist among us a number of practitioners who in their old age, through broken health or ill fortune, find themselves in the saddest of circumstances with no one to whom they can appeal for help. The Fund also extends help to widows of medical men and daughters who in later years find themselves without means of support, and these cases are among the most poignant. Further the grants are not made on any surface aspect of the requests for help; all cases are investigated carefully to ensure they represent genuine distress before a grant is made, and anxious care is taken that the necessary precautions against abuse should be conducted with sympathy and delicacy—not an easy task but one that is rendered easier because undertaken by persons with full knowledge. Annuities are given only in the circumstances where there is no possibility of affairs mending, and the highest annuity which can be given at present is £40 per annum, which often does not meet the real seriousness of the position. But the deep gratitude expressed by the beneficiaries, not only for such substantial support but also for the slight augmentations received from the sharing up of the Christmas Fund and the material donations from the associated Guild, combine to prove the status of deep poverty on which many of our brethren are compelled to exist.

The centenary occasion affords a poignant opportunity for the setting right of this position, and it is to be sincerely hoped that the whole

profession may recognise this and rally to the support of the Fund. Next Tuesday comes the statutory annual meeting, but there will be in April a general appeal to the profession setting out the claims of the Fund to larger and more general response. The appeal will have behind it the long history of a charity greatly needed and admirably administered. None should fail to see its force, and, incidentally, no one need delay until April before giving support.

TREATMENT BY PROLONGED NARCOSIS

THE psychiatric use of prolonged narcosis has lately had a wider vogue in this country because of the Cardiff work on insulin as a protective against poisoning by the narcotics employed. Dr. PARFITT's paper in our issue of Feb. 22nd must be read, however, as a warning against too easy confidence in such precautions. His series of carefully treated patients showed alarming toxic symptoms, which were as common in those who received insulin as in those who had only glucose in addition to the narcotic somnifen, and 3 of his 56 patients died. So risky a method of treatment is plainly unsuitable for general application, unless the advantages can be clearly demonstrated.

The situation is in some respects parallel to that arising when malaria was introduced into the treatment of general paralysis. Widely different in efficacy, the two methods have this in common, that there is no precaution, no routine procedure in their administration which can take the place of special experience in their use, or good clinical judgment in selecting cases and supervising the course of the therapy. This may well be seen in the various publications from Burghölzli, the clinic in which the method was first employed by KLAESI. In the first year, 1920, three patients died. From then till 1927, when OBERHOLSER published the experience of the clinic, there was not a single death among the large number of cases treated. Variations in the technique were tried, and in 1929 all oral ingestion was stopped during the 10-14 days of the treatment; fluids being given by the rectum instead. Dial, Luminal, and other narcotics were urged besides somnifen, and LUTZ reported the rather satisfactory results. Then, in 1930 a mixture suggested by CLOETTA, who had been responsible for the original proposal to KLAESI in 1920, was introduced, and the outcome has been gratifying.¹ The precautions taken by the very experienced physicians and nurses of the hospital have been exceptionally detailed; to read of the many points to which they have learnt to direct their attention is to recognise the need for expert handling of the method if its risks are to be minimised and its best effects secured. Yet even in these accomplished hands there have been mishaps. Of 125 narcoses, carried out on 84 schizophrenic patients between 1930 and 1934, two ended fatally, and others caused much concern.

¹ Cloetta, M., and Maier, H. W.: *Zeits. f. d. ges. Neurol. u. Psych.*, 1934, cl., 146.

In appraising these results, however, it must be borne in mind that the method was more thorough and drastic than that usually employed in England. In a mitigated form, continuous narcosis can in careful hands be employed extensively and safely. Dr. P. K. McCOWAN, who states that at Cardiff City Mental Hospital it is rarely found necessary to give more than 4.0 c.cm. in the 24 hours, reports in our issue of Feb. 29th (p. 508) that 154 cases have been treated without a single fatality, and in an English psychiatric clinic it has been much and profitably used for eight years, likewise without a death. The value of the method can best be estimated by noting the number of hours of

sleep obtained with the drugs over a fixed period, and the outcome in adequate numbers of patients with particular varieties of mental illness and of well-investigated prognosis. The recent paper of MONNIER,² also from Burghölzli, is excellent in this regard, as also for the discussion of precautions, mechanism of improvement, and course of the narcosis. It might with some reason be urged that no one should undertake this sometimes dangerous method of treatment, with or without insulin, until he had familiarised himself with the exceptional knowledge of the physicians at Burghölzli, available in their publications.

² Monnier, M.: *Nervenarzt*, November, 1935.

ANNOTATIONS

THE PORTAL OF MEDICINE

THE three volumes¹ sent us at this time of year by the Registrar of the General Medical Council always contain food for thought. Last year we remarked that the number of new qualifications had risen steadily since 1929 and was 40 per cent. above the entry which seemed to meet requirements in pre-war days. The figure was then 1664. It is now 1884; and since there is also an increase in the number of medical students registered—last year 2350, this year 2603—on which turns the number of qualifications after a 5-6 year interval, evidently the engorgement of the medical profession is continuing and indeed increasing. In May last as we anticipated the position was considered by the General Medical Council, when Sir Norman Walker recited the figures and commented upon them. "I recall," he said, "our past experience that, when trade is bad, entries of medical students go up, and vice versa. There are schools which are conscious of the fact that their equipment and staff are being severely strained, and that they must consider limitation of entry. But there is a general feeling of hope in the air to-day, and perhaps the severe limitations under consideration in some places may not be necessary. There will not, I feel sure, be any tendency to lower the standard of entry even if numbers do go down a little." But if the analogy from past experience still held, there should have been a diminution in the number of students entering last year, at all events in the latter half, for by that time the trough of trade

¹ The Medical Register for 1936 (21s.); the Medical and Dental Students Register for 1935 (7s. 6d.); the Dentists Register for 1935 (12s.); all published for the General Medical Council by Constable and Co., Ltd.

depression was already a year or more in the past. It may be that the lag is longer than this and that the prospect of better commercial openings may only now be beginning to divert school-leavers away from medicine. It is clear enough that the suggested limitations of entry to medical schools cannot generally have been put into force, although everywhere the raised standard has been maintained.

In one respect the entry is still abnormal. For several years past the number of medical students gaining access to the students' register by virtue of study abroad has been well over a hundred, the influx being preponderantly from German universities. In 1935 111 of the 122 names so registered implied German origin and, with slight exception, they are the names of men and women—for many of them are women—who began their medical study ten, twenty, or even more years ago, and may be presumed to have already practised medicine in the country of their origin. Very few continental refugees, if the students' list can be taken as a guide, are studying medicine from the outset at English or Scottish schools. The influx of unfortunate refugee practitioners seeking registration here can hardly continue long. Many who resent

or fear their competition in medical practice might have less reason to object to a foreign element in dental study where the number of entries, though rising, is still quite insufficient to cover the death or retirement of the immense group of middle-aged dentists admitted under the Dentists Act of 1921. The increment of 14 dental students in 1935 is entirely covered by the 24 who came from Germany. Turning to the additions to the Medical Register itself it may be

noted that there is an increase in every section; the surplus of 220 over last year's increase is made up of registrations in England 124, Scotland 38, Ireland 23, Colonial 23, Foreign 12. It is many years since as many as 19 names have been added in a single year to the Foreign section of the Register; they are all admitted on Italian qualifications although in only 6 cases has the name an Italian sound.

This and much more of the trend of medical polity can be gleaned from these three volumes which contain, as always, that recital of the Medical and Dentists Acts which should be studied as closely by those within the profession as they are by those without. The graphic picture has been again brought up to date and may spare a number of words in setting out the situation.

PHYSICAL MANIFESTATIONS OF EMOTION

THE changes in the body which accompany emotion have not yet been fully explored. The cruder manifestations of anger and fear, which all may witness and experience, were illuminated by the researches of W. B. Cannon and the part played by the vegetative nervous system and the suprarenals in producing these familiar outward signs of emotion is now established. But it is doubtful whether in their daily practice doctors give sufficient regard to the physical phenomena that can be laid to the door of an emotional disturbance. It would be unjust to conclude that this neglect of the psychogenic is the outcome of faulty habits of thinking about disease or faulty teaching. It is in large measure due to the vagueness of these psychosomatic relations, the lack of precise information as to the more restricted changes which may occur within one or other bodily system, and the way in which "emotion" is talked of in the round, whereas it is particular emotions, with their specific psychic quality and causation, that have clinical significance. As long as it seemed that diarrhoea, for example, might be a manifestation of fear, that constipation might also be attributable to this affect, and that either might be due to other affects as well, the adequacy of simple psychogenic explanations for such a disorder as diarrhoea remained suspect. Doubtless also the difficulty of distinguishing between the common, quasi-universal manifestations of affect and the personal individual ones has been a stumbling-block. The psychiatrist, however, is continually impressed by the frequency with which functional and even plain structural changes in the body can be traced back to emotional upsets, sometimes transient, sometimes lasting. In his concern for individual experiences, and psychological causes, he may sometimes, indeed, overlook the importance of the physiological happenings which are, more or less inevitably, set going by an affective happening to such effect that they become independent of their origin and proceed according to their own laws of succession. It is clearly profitable for all physicians, whether psychiatrists or not, to have at their disposal a comprehensive survey of what is known concerning the influence of emotions on the functions of the various organs of the body. A monograph has lately been written by Dr. Erich Wittkower,¹ which covers the literature of the subject and describes his own researches, carried on for several years in the medical clinic of the Charité in Berlin and latterly in the central pathological laboratory at the Maudsley

Hospital. So diligently has this author studied the work of others that his bibliography is gargantuan; and his own investigations have covered a very wide field. The respiratory and circulatory systems, salivary and biliary secretion, the stomach, the blood, the urine, and the thyroid gland are reported on in detail, as is also the psychogalvanic reflex. Dr. Wittkower indicates the significance of the relationships discussed for any interpretation of the findings in internal medicine as well as in the neuroses; though in his excursion into the latter field he is sometimes guilty of over-simplification of the problems. However, the monograph is not designed only for psychiatrists; it provides a detailed conspectus whereby physicians as a whole may make themselves acquainted with the large, though still inadequate, body of knowledge embedded in a polyglot multitude of publications.

MYCOSIS FUNGOIDES

VYING with pemphigus in its malignancy, and equally intractable and uncertain in its reactions to all forms of treatment, mycosis fungoides, in spite of the immense amount of work that has been lavished upon it, remains an unsolved problem. Fortunately like pemphigus it is an exceedingly rare disease, and even the large skin clinics do not see more than one or two cases in as many years. It owes its name to Alibert, who first described it in 1814, long before the term "mycosis" had assumed the significance it holds to-day. As far as we know the symptoms are not due to a mycotic or fungous infection, and the second appellation also is adjectival only, and descriptive of the fungating character of the third and usually terminal stage of the disease. Of the published cases 75 per cent. have occurred in men in the fourth decade of life, and very few of these have survived the fifth. The first or premycotic stage may resemble an eczema or psoriasis so closely that the most experienced are commonly misled. It may last for years with intensely pruritic patches, which nothing but X ray treatment will relieve. This feature should tend to arouse our suspicions of the underlying cause of the symptoms, which may be further enlightened by microscopic examination of the sections. In the second, or stage of infiltration, there is a cushion-like soft elevation of the patches, which become rather more sharply outlined, and as they spread outwards in a circular or gyrate fashion tend to coalesce. In so doing they demarcate or surround residual islets of healthy skin, which are thus roughly angular in outline and highly characteristic in the clinical picture. The third stage is that of ulceration of the extending patches of infiltration, which often reach the size and conformation of tumours. These are always soft and the term "tomato" describes them with some accuracy. They are usually exceedingly sensitive to quite small doses of X rays ($\frac{1}{4}$ - $\frac{1}{2}$ S.B. dose). Only one or two should be treated at a sitting for fear of undesirable effects from too rapid absorption of toxic substances. Hitherto X rays have been the only reliable weapon in treatment, and even these fail eventually in the large majority of cases to do more than postpone the inevitable exhaustion from ulceration and secondary sepsis. As in several other dermatoses improvement has sometimes been observed to follow pyrexia both accidental and artificially induced, and Dr. H. MacCormac now reports a case¹ in which the method of malarial therapy, as for G.P.I., was twice

¹ Jour. of Ment. Sci., 1935, lxxxii., 533.

¹ Proc. Roy. Soc. Med., vol. xxix., February, 1936, p. 238.

successful after all other measures had failed. The author confidently asserts that "without this treatment he would have died." The improvement was certainly sustained from May, 1934, when he was demonstrated to the dermatological section of the Royal Society of Medicine, to the present day. It is of course much too soon to claim a cure, but the method is accessible nowadays in any large hospital, by courtesy of the Ministry of Health, and is well worthy of further trial. It may not be out of place to remind our readers that most diagnosed cases of mycosis fungoides have already been subjected to prolonged or frequently repeated X ray treatment, as a result of which they may have developed anæmia and leucopenia of variable degrees. Due consideration of the differential blood count should therefore always precede the malarial inoculation.

THE TREND OF POPULATION

IN the course of three public lectures lately given in the statistical department of University College, London, Dr. R. Kuczynski, well known to students of vital statistics for his extensive work on population problems, spoke of the past and possible future trend of population growth in different parts of the world and the close bearing this trend has on the economic problems of the day. Over the past century and a half he finds that the white population of the world has increased at an average rate of nearly 1 per cent. per annum. This increase has been due to the decline in mortality following on advance in the standard of living and in the art and science of medicine. Such factors have led to nearly a doubling of the expectation of life at birth in the countries of western and northern Europe. This extension of the average duration of life is, however, as is generally recognised, due largely to the vast improvement during the twentieth century in the infant mortality-rate and in the ages of childhood and young adult life. At more advanced ages, 60 years and over, there has been relatively little improvement, as is shown in the new English life table on p. 686, and it is possible that we are just as incapable of extending life at these ages as were our forefathers. Kuczynski takes the view, therefore, that future population trends will depend mainly upon fertility and not, as in the past, upon changing mortality. Whether fecundity—that is, reproductive power—has changed in the course of years is a controversial question. There is no evidence, except for France, that fertility in marriage was lower until the middle of the nineteenth century than in former centuries, and the decline of fertility in recent years is in Kuczynski's opinion almost certainly due to the deliberate restriction of births. The best measure of the present rate of growth he takes to be the net reproduction-rate—the number of future mothers derived from present mothers. By that measure all countries of western and northern Europe, the United States, Australia, and New Zealand are failing to reproduce themselves. At present rates in western and northern Europe 100 women give birth to only 76 future mothers. The population of England and Wales will probably increase for another seven years and then decline, with an increasing proportion of persons in the older age-groups. In 1881, persons of 60 years or more formed only 7 per cent. of the total population; in 1931 they comprised 11 per cent.; and by 1981, if the present trend continues, they will have risen to 22 per cent. Very little improvement in the reproduction-rate could be derived from an improvement of the mortality-rate

of women in the childbearing ages, or in a higher marriage-rate, or in an earlier age of marriage than at present. Increased fertility can only be brought about, Kuczynski believes, by less birth control. Better economic conditions would not necessarily achieve this, for fertility began to fall while the standard of living in this country was still rising, and the economic incentives applied in Italy appear to have been a complete failure. It is too early to say yet whether action in Germany is likely to be effective, but she is relying rather upon the inculcation of new ideas than upon economic advantages. A general desire for more children seems to be the only hope of increasing fertility, and it hardly appears likely, with the world in its present state of instability, that that desire is going to develop. In addition the general attitude on questions of population has radically changed. Twenty-five years ago the prospect of a decreasing population in this country would have been viewed with alarm; now, with widespread unemployment, we are far more afraid of over-population. Whether those fears are justified Kuczynski is more than doubtful. Under-population, by limiting consumption and economic development, may possibly be as powerful a cause of unemployment as over-population. It may well appear that Mr. Smith the builder is better off by having only one child, but he is only better off so long as other people have, say, three, and therefore create a demand for his services.

There is no doubt, as Lord Dawson pointed out in introducing Dr. Kuczynski, that these problems of the growth of peoples are closely linked with all the social and economic questions of the day, and the lecturer gave his audience much to think about.

TREATMENT OF PERIPHERAL ARTERIAL OBSTRUCTION

METHODS for the passive exercising of blood-vessels in a limb which is the site of arterial obstruction, for example, contrast baths, have been in use for a long time. More recently an apparatus for alternately increasing and reducing the air pressure on the limb has been used with the same object and strong claims have been made in its favour. Some of these claims are critically reviewed by E. V. Allen and G. E. Brown¹ who are well known for their work on arterial disease. It is admitted that alternate pressure and suction (sometimes referred to as "pavæx," signifying passive vascular exercise) is able to increase the blood flow in a limb, both when normal and when the seat of some vascular obstruction, since this procedure causes a definite increase in skin temperature, which may last up to 72 hours. However, though there is no evidence that the blood flow can be increased permanently by this means, a transient increase repeated frequently might be expected to relieve symptoms. Published reports indeed suggest that with this treatment indolent ulcers may heal, rest pain may be relieved for variable periods, intermittent claudication is usually benefited, while gangrene can be avoided in cases of sudden arterial occlusion if the treatment is begun early enough. From their experience of 60 cases the authors are able to confirm these results only in part; they found more benefit in the pain of ischæmic neuritis than in the pain accompanying trophic lesions, while in one case of sudden arterial occlusion gangrene developed in spite of treatment begun within a few hours; the pain was, however, relieved. In intermittent claudication no improvement was

¹ Jour. Amer. Med. Assoc., 1935, cv., 2029.

noted. The conclusion drawn from the total results is that though passive vascular exercise has its uses in arterial disease it has yet to be shown that its value, except perhaps in ischaemic neuritis, is greater than that of other conservative measures. It may also be a suitable method in older patients for whom protein shock and sympathectomy might be considered inadvisable.

CHANGES IN THE BREAST DURING THE MENSTRUAL CYCLE

Dr. Howard C. Taylor,¹ of New York, has made a serious effort to determine how far the clinical changes in the breast associated with menstruation are related to histological changes. The views hitherto expressed are notoriously conflicting, some observers having reported what almost amounts to a complete reconstruction of the glandular elements of the breast with each menstrual period and their disappearance in the intervals, while others deny the evidence for epithelial proliferation and retrogression. It may be recalled that three years ago in our own columns Dr. Helen Ingleby² described cyclical histological changes as occurring, not only in normal breast tissue, but in tumours of the breast. Thus she regarded fibro-adenomata as owing their development to local interference with the normal process of intermenstrual involution. Cystic mastitis was in her view the result of irregularity in the cyclical changes in the breast, while the variations in histological appearances of carcinoma depended on the degree to which the cells of the lobules had undergone a malignant change whereby they lost their power of postmenstrual involution.

The difficulty of obtaining normal material is at once evident—particularly material from cases in which a reliable menstrual history is available. Taylor makes his observations on tissues from four sources: (1) apparently normal parts of breasts of 41 patients operated on for disease processes in other parts; (2) breasts, or parts of breasts, removed because of pain at the periods; (3) a few hypertrophied breasts which were available for histological study; and (4) gross sections and histological examinations made in a few cases of secretion from the nipple. His first conclusion is that "normal" breast tissue shows much variability of the glandular elements without relation to the stages of the menstrual cycle, and that no epithelial proliferation typical of any stage can be recognised. In one patient portions were removed from identical parts of the two breasts, one section being made 14 days after the last period, and the other on the day that menstruation began; yet there was no detectable difference in the degree of acinar development, although the case was one in which a painful hypertrophy of the breasts occurred at each menstrual period. The most constant findings recorded are cyclical intracellular changes, leading to blurring of the cell outlines; and oedema of the interlobular connective tissue, due to premenstrual hyperaemia and leading to sharper definition of the lobules. Taylor believes that those observers who have described a definite epithelial proliferation in the premenstrual period have formed their opinion without sufficient regard for the normal variations, and in particular for the age variations, of the material examined. Painful breasts may or may not show diffuse areas of induration. Even with a fairly well-marked nodularity, histological examination may show little to distinguish

the section from normal breast tissue. Oedema or a slight localised hypertrophy must here account for the signs and symptoms. Increased density of the connective tissue does occur in some cases, and may be associated with an actual diminution in the size of the lobules. The findings in the painful hypertrophies were much the same. Some showed a normal histology; in others there was an increase in fibrous tissue. Signs of epithelial proliferation and of cystic formation were uncommon; areas containing "disappearing lumps" were found to differ little from the normal. The cases of discharge from the nipple did, however, show definite changes in the glandular elements. The ducts were widely dilated, and were filled with amorphous material; the acini were more numerous, and the duct epithelium might appear active, even filling the lumen in places, or forming papillomata. Evidence of catarrhal inflammation and fibrosis was sometimes found in these cases. Secretory activity seemed to bear no relation to the menstrual cycle. Non-puerperal lactation is, of course, distinct from the type of discharge associated with duct changes; but chances to study this condition histologically are uncommon.

MORE RADIUM WANTED

THE sixth annual report¹ of the National Radium Commission expresses a belief that at least another 20 grammes of radium could be used to reinforce the routine work of existing centres throughout the country and to provide larger units for special work. The recommendation may come as a surprise to careful readers of earlier reports who will have noticed the guarded tone which the Commission has adopted towards the use to which the national supply of radium has been put at certain centres and particularly towards the larger units of radium element. The long delay in the issue of this report can hardly be attributed solely to the eviction of the Commission from its pleasant offices in the Adelphi and may be associated with the need for unanimity felt by the Commission before issuing so important a recommendation. It is not long since many of those who know most about the properties of radium were still feeling that some of it might have been left more safely on the Belgian slag heaps than distributed where the knowledge and responsibility for its clinical use were still imperfectly developed. The delay will have enabled the five new members of the Commission—Dr. Thos. Carnwath, Dr. T. Ferguson, Dr. Robert Hallam, Prof. J. C. G. Ledingham, F.R.S., and Prof. James Young—to take their share in the decision. Reports from national radium centres this time contain much reason for contentment. Whole-time radiologists and physicists have been appointed, follow-up departments have been so active that almost every patient treated has been traced, reorganisations have been carried out, and generally the Commission's policy of centralisation, coöperation, and documentation has been realised. In the words of the report, "the national centres provide evidence of a determined effort on the part of the authorities concerned to fall in with the Commission's ideal of a national scheme," and although the number of regional centres has not been increased, four hospitals with radium departments have been recognised by the Commission. In fact just as the centres are actually becoming progressive, and just as the Commission is drawing upon the last available supplies, it

¹ Surg., Gyn., and Obst., Feb. 1st, 1936, p. 129.

² THE LANCET, 1932, ii., 835.

¹ Sixth Annual Report of the National Radium Trust and Radium Commission, 1934-1935. Cmd. 5112. H.M. Stationery Office. 9d.

is being asked for larger and larger quantities of radium. Turning to the use of larger units the report states that the work of the three 1-gramme units has proceeded without interruption, while the standing clinical committee has reported that this form of treatment is of definite value. There is only one 5-gramme unit known to be in use at the moment in Great Britain. The investigation of beam therapy is being followed by the Trust "with great interest." So far it has been limited to carcinoma of the head and neck, but with results sufficiently promising to justify the continuance of the investigations. This is in brief the background set out in the report to justify the Commission's desire for more radium. The public has never been backward in providing more when called upon to do so and no doubt it will be forthcoming.

THE PRICE OF MILK FOR HOSPITALS

In the House of Commons on Feb. 17th Mr. Thomas Johnston complained that the policy of the Government, by raising the price of milk supplied to hospitals, clinics, and poor-law institutions, was increasing their already serious difficulties. He asked the Minister of Agriculture to restore the price to that charged before the inauguration of the milk marketing schemes. In Glasgow the local authorities and voluntary hospitals have been agitating for two years for cheaper bulk supplies of milk from the Scottish Milk Marketing Board. They have shown that the city corporation is now paying £13,000 a year more than before the scheme come into force, while a voluntary hospital such as the Royal Infirmary is paying an extra £1500. Last week a committee of the corporation met to consider a letter received from Sir Godfrey Collins, Secretary of State for Scotland, who wrote that he would not be justified in asking the Milk Board to reduce the price to hospitals merely on the ground that this price had been raised by the elimination of price-cutting competition. The Board, however, would be prepared to agree to a 50 per cent. reduction in the price of any milk bought by hospitals in excess of last year's supplies. The corporation's committee expressed dissatisfaction with this reply, maintaining that the offer of a lower price conditional on increased purchases is of little value because the patients are already getting as much milk as they can consume. They decided to ask the Secretary for Scotland not to make a final decision until the report of the Reorganisation Commission on Milk Marketing has been issued.

Lord Willington, the retiring Viceroy of India, has been selected to be chairman of the St. George's Hospital rebuilding fund.

THE death is announced from Washington of Dr. William Holland Wilmer, the prominent American ophthalmologist, director of the Wilmer Ophthalmological Institute.

ON Tuesday and Thursday, March 24th and 26th, at 5 P.M., Mr. Joseph Needham, Sc.D., will deliver the Oliver-Sharpey lectures to the Royal College of Physicians of London. He will speak on chemical aspects of morphogenetic determination.

WE regret to announce the death of Sir Kedarnath Das, of Calcutta, principal of the Carmichael College and author of "The Obstetric Forceps" and other well-known works on midwifery and gynaecology.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surgeon Rear-Admiral Bryan Pickering Pick, O.B.E., has been appointed Honorary Surgeon to the King from Jan. 16th, 1936.

Surg. Comdrs. F. L. H. MacDowel to *Excellent*; K. A. J. Mackenzie to *Drake* for R.N. Hosp., Plymouth; and J. C. Souter to *Pembroke* for R.N.B.

Surg. Comdr. G. S. Harvey placed on the Retd. List at own request with rank of Surg. Capt.

Surg. Lt.-Comdr. H. J. McCann to *Pegasus*.

Entered as Surg. Lts. (D.) for Short Service: A. F. Ferguson, J. B. Morris, H. P. L. Rhodes, and D. N. Williamson.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. W. D. M. Millar promoted to Surg. Lt.-Comdr. Surg. Lt. R. Cormack to *Royal Sovereign*.

ROYAL ARMY MEDICAL CORPS

Maj. P. A. Stewart retires on ret. pay.

ARMY DENTAL CORPS

Capt. I. A. Barlow to be Maj.

TERRITORIAL ARMY RESERVE OF OFFICERS

Maj. H. H. Fowler, from Active List, to be Maj.

ROYAL AIR FORCE

Squadron Leaders H. W. Corner to R.A.F. Depot, Uxbridge, and V. S. Ewing to No. 9 Flying Training School, Thornaby, for duty as medical officers.

Flight Lt. G. S. Strachan is promoted to the rank of Squadron Leader.

Flight Lts. W. G. S. Roberts to R.A.F. General Hospital, Hinaidi, Iraq, and J. A. Kersley to Princess Mary's R.A.F. Hospital, Halton.

Flying Offrs. D. S. M. MacArthur to No. 10 Flying Training School, Tern Hill; C. F. R. Briggs to Home Aircraft Depot, Henlow; L. M. Crooks to Princess Mary's R.A.F. Hospital, Halton; D. J. Sheehan to Central Flying School, Upavon; H. D. Conway to No. 1 Flying Training School, Leuchars; W. J. Fowler to No. 2 Flying Training School, Digby; R. F. Wynroe to No. 5 Flying Training School, Sealand; E. B. Harvey to No. 7 Flying Training School, Peterborough; and I. K. Mackenzie to No. 9 Flying Training School, Thornaby.

Dental Branch.—Flying Offrs. R. M. Brown to Headquarters, R.A.F., Cranwell, and W. E. Nelson to Air Armament School, Eastchurch.

INDIAN MEDICAL SERVICE

Lt.-Col. W. E. R. Williams, O.B.E., to be Col.

The promotion to the rank of Maj. of the under-mentioned officers is confirmed: M. S. Gupta, R. Linton, and H. W. Mulligan.

Lt.-Col. J. Scott, D.S.O., O.B.E., I.M.S., has vacated the appt. of Surg. to H.E. the C.-in-C.

The undermentioned appts. have been made:—

Surg. to H.E. the C.-in-C.: Maj. E. P. N. Creagh, R.A.M.C.

A.D.M.S.: Col. W. J. Powell, C.I.E., Col. S. G. S. Houghton, C.I.E., O.B.E., and Col. D. C. V. Fitzgerald, M.C.

D.A.D.H.: Lt.-Col. J. C. Chukerbuti.

IN deference to the King's wish that public functions connected with the sciences and the arts should not be cancelled, it has been decided that the biennial dinner of the Royal Society of Medicine shall be held at the May Fair Hotel on Wednesday, May 6th, at 7.30 for 8 P.M. Sir Kingsley Wood and Mr. Philip Guedalla will be among the guests.

PROGNOSIS

A Series of Signed Articles contributed by invitation

XCIII.—PROGNOSIS IN MEASLES

MEASLES is the biennial "scourge inexorable" of small children in great cities. The causal agent of the symptom-complex so graphically described by Sydenham and so familiar to every mother that it is apt to breed contempt is generally considered to be a filtrable virus. It is, however, not the virus, although this prepares the way, but the associated bacterial infections of the upper respiratory tract which makes measles one of the lethal diseases of early childhood. In recent epidemics in London these organisms have been chiefly strains of the hæmolytic streptococcus; much less usually, pneumococci and the *H. influenzae* of Pfeiffer have been recovered from swabbings of the nasopharynx of measles patients admitted to hospital. Means of protection of the child population by active immunisation are yet to seek. P. Stocks has shown that some children acquire, during an epidemic, without overt clinical attack, a measure of latent active immunity which may tide them over until the next visitation; in a few the immunity so attained would appear to be permanent. Although a number of cases of measles in the new-born infant infected by the mother are on record, temporary passive immunity, transmitted through the placenta, is the prerogative of nearly all infants at birth. It lasts in full force for the first three months and then gradually wanes. By means of the injection of convalescent or adult immune serum, temporary protection may also be afforded at any age. With few exceptions, solid active immunity is only to be purchased at the price of a clinical attack the severity of which, it is true, may be mitigated by the injection of human immune serum. Serum-attenuation apart, the age of the child at the time of attack, its nutrition and environment before and during the illness, and the season of the year at which this takes place are factors of the utmost importance in prognosis.

Age

For the reason already stated, infants under 3 months of age, however intimately exposed, generally escape attack. The waning of maternally transmitted immunity is to be observed in the attenuated attacks which may occur from the third up to the sixth or seventh month. By the eighth month the infant is at full risk not only from the virus of measles, but, of course, from his constant enemy broncho-pneumonia reinforced by the virus. The toll of life from this complication of measles is greatest during the first two years; the fatality-rate then falls with each succeeding year of age and among children over 5 is small. During the 1933-34 epidemic the fatality-rate at all ages of 12,730 patients admitted to the measles wards of the fever hospitals of the London County Council was 5.1 per cent.

Nutrition.—Environment.—Season

Both the severity of the attack and the likelihood of complications are enhanced among children whose diet has been deficient in vitamins. The prognosis of active rickets, measles, and broncho-pneumonia in conjunction is, to say the least, not very hopeful. The addition of extra vitamins A and D to the diet during the attack is, however, as Dr. Helen Mackay showed in the wards of this hospital, without effect.

Hardly separable from nutrition is environment; the two so often go hand in hand. Halliday showed that in the crowded tenements of Glasgow the maximum incidence of measles fell upon children under school age; in working and middle-class households upon those between 5 and 10 years; and among the public school class at still later ages. When it is added that he estimated the fatality-rate at ages up to 2 years at from 10 to 20 times greater than that which obtained between the fifth and tenth year, the influence of environment upon prognosis is obvious. The older age at which the public school class, due to a sheltered childhood, is attacked may not be an unmixed blessing. A. I. Simey, when at Rugby, preferred outbreaks of measles little and often rather than extensive epidemics which occurred at longer intervals, and strained the sanatorium accommodation.

Epidemics of measles ordinarily commence in October or November, the maximum prevalence being attained during the first quarter of the new year. A late start and therefore a climax reached when seasonal conditions are less favourable to the occurrence of broncho-pneumonia must clearly tend to a reduction in the incidence of this complication and therefore the number of deaths.

Clinical Factors

Epidemics of measles, *qua* measles, like those of other specific infections, vary in severity. Toxic cases may be few or many in individual outbreaks, but death purely from toxæmia is uncommon. On the whole, the belief of the old nurses that a brilliant and profuse rash is of favourable import is justified. The dusky, velvety, maculo-papular eruption, which may be relatively sparse, is of bad omen, whilst true hæmorrhagic measles with bleeding from mucous membranes, now rarely encountered, is almost invariably fatal. Pyrexia in measles starts with the onset of the catarrhal stage and persists until the rash begins to fade. A temperature of 104° F. or more during the eruptive stage is not inconsistent with an uncomplicated attack especially if the rash is robust. But should the temperature not fall with the fading of the rash or should it again rise appreciably after an interval of hours or days, the coexistence or development of one of the major complications must be suspected. The common ones, each due to an extension of the concomitant bacterial infection of the upper respiratory tract to mucous membranes rendered more vulnerable by the virus are three: broncho-pneumonia, enteritis, and otitis media. All three may coexist or may follow speedily one after the other, the commonest sequence being in the order named. Ordinarily beginning during the eruptive period, broncho-pneumonia and enteritis are occasionally late complications. Otitis media may also occur quite early in the attack, especially if the middle ear has been previously damaged, but its incidence is more usual during the second week of the disease.

BRONCHO-PNEUMONIA

Prognosis in broncho-pneumonia depends primarily upon the general factors already discussed, and secondly upon the stage at which the patient comes under treatment. Too often practitioners are called in to treat the broncho-pneumonia of measles only

when the condition is far advanced and the prognosis hopeless. The first requirement of *any* measles patient is an abundance of fresh air, which may be quite unobtainable in his home. Provided that bodily warmth is maintained and there is protection from rain, the child suffering from broncho-pneumonia is best nursed under the open window or upon a balcony. For the desperate case it may be deemed necessary to administer oxygen; if so, the funnel method is merely wasteful; administration by nasal catheter is an improvement but far from efficient. Observation has led me to the conclusion that failing Poulton's or some other type of oxygen tents (which are now available in all the infectious diseases hospitals of the London County Council) circulating air from an open window is preferable to oxygen from a funnel or catheter. It need not be added that the condition of the right heart must be watched and improved by cardiac drugs such as coramine nor that, if the temperature fails to drop with the abatement of the broncho-pneumonic process, the presence of pus must be suspected, probably in the pleural cavity but possibly in the middle ear or mastoid antrum.

ENTERITIS

The clinical diagnosis is obvious; bacteriologically, non-lactose fermenters are rarely found; the enteritis has resulted from the swallowing of muco-pus derived from the upper respiratory tract. Prognosis depends upon the promptness with which dehydration is countered and the coexistence or not of broncho-pneumonia.

OTITIS MEDIA

From the point of view of the physical and educational future of the child, rather from that of its immediate effects, otitis media is the most important complication of measles, since, if neglected, it is a potent cause not only of chronic ill-health, but of deafness and deaf-mutism. Promptly and adequately treated, the prognosis as regards a healed drum-head and unimpaired hearing is favourable. The advice of an otologist should be sought as soon as possible in every case of otorrhœa in measles. A number of cases of catarrhal otitis media occur and subside spontaneously without perforation, but when perforation does occur it may be with so little warning that primary paracentesis is out of the question. Mastoiditis is of rare occurrence if the middle ear is treated early and upon proper lines; otogenic meningitis is an occasional sequel of mastoiditis.

Among the less common complications of measles which may affect prognosis the following must be noted.

LARYNGITIS

Towards the end of the catarrhal stage laryngitis sometimes causes such a degree of obstruction to the airway that tracheotomy is contemplated and has, on occasion, been performed. Provided that laryngeal diphtheria can be excluded, the operation is better avoided not only because the results are almost uniformly bad, broncho-pneumonia being a nearly inevitable sequel, but also because in most cases the severity of the laryngitis abates as the rash appears. The child should be placed in an atmosphere of steam, and although, in the absence of diphtheria, the effect must be non-specific, a moderate dose of antitoxin (16,000 units) frequently appears to afford relief in a few hours. Laryngitis which persists into convalescence probably indicates ulceration which may ultimately result in stenosis; expert advice should be sought.

CORNEAL ULCER

Pronounced conjunctival injection and photophobia are of common occurrence in the catarrhal and early eruptive stages and the conjunctiva thereafter is prone to bacterial invasion which may be minimised by daily nursing attention to the eyes. Corneal ulcers even when promptly treated leave nebulae which, if central, may impair vision permanently; if they are not promptly treated, panophthalmitis and possibly sympathetic ophthalmia may result. Daily attention reduces the incidence, too, of the minor but tedious infections of the lids, blepharitis, hordeolum, and chalazion, to which measles patients are liable.

AFFECTIONS OF THE BUCCAL MUCOSA

In many cases of measles, especially in infants, the erythematous-pultaceous stomatitis of Comby may be troublesome during the catarrhal stage, but usually subsides with the exanthem; it may persist and become ulcerative. This is a serious condition which may result in the death of the child from septic absorption or from aspiration broncho-pneumonia. Attention must be drawn also to the significance in measles of the Plaut-Vincent infection of spirochæte and fusiform bacillus; this may involve the mucous membranes of the buccal cavity during the convalescent stage in debilitated children. The complication may take the form of Vincent's angina, stomatitis, or gingivitis, and unless promptly treated, preferably by injections of N.A.B. and local applications of potassium chlorate, may result not only in great debility but by extension to the mucous membrane of the cheek in the dreaded, but fortunately rare, cancerum oris. When this supervenes nothing short of surgical measures may avail to save life.

ENCEPHALITIS

Encephalitis, possibly due to the activation of an existing virus infection by the virus of measles, is a rare but serious complication which may occur at any stage of the attack, but most usually as the rash is fading. Pyrexia, drowsiness, and convulsions passing into stupor, together with muscular twitchings, are characteristic. This syndrome may clear up completely without residual damage or may be followed by spastic paralyse and other manifestations of damage to the central nervous system (see F. R. Ford, Bull. Johns Hopkins Hosp., 1928, xliii., 140, for an analysis of cases in the literature and a full clinical description).

Associated Specific Infections

Concurrent whooping-cough is not unusual and increases the liability to broncho-pneumonia. Diphtheria, which may involve the larynx, is obviously a severe additional handicap. Scarlet fever, chiefly because it implies the addition of other strains of the hæmolytic streptococcus to the flora of the upper respiratory tract, increases the likelihood of otitis media. If there is reason to suppose that the measles patient may have been exposed to diphtheria or scarlet fever it is wise to inject at once a prophylactic dose of the appropriate antitoxin, Schick and Dick tests being omitted in young children. It is still wiser to combine the two antitoxins in one injection containing in 5 c.cm. 2000 units of diphtheria antitoxin and about 4 c.cm. of scarlet fever antitoxin. Diphtheria and scarlet fever patients who have been exposed to measles should receive convalescent or adult immune serum, preferably with the aim of

FOOD, HEALTH AND INCOME

A NATIONAL SURVEY OF NUTRITION

For the first time the food position of the country has been surveyed on a large scale to show the relationship of income, food, and health. The investigation, which relies largely upon statistical methods, has been undertaken by the staff of the Rowett Institute in coöperation with the staff of the Market Supply Committee. It is described by Sir John Orr, M.D., F.R.S., director of the institute.¹

Instead of discussing minimum requirements, about which there has been so much controversy, the report considers optimum requirements. These are based on the physiological ideal, defined as "a state of health such that no improvement can be effected by a change in the diet," and the standard of adequacy of diet adopted is one which will maintain this standard of perfect nutrition.

The survey attempts to find out the proportion of the population attaining this standard; and the state of health of the country is reviewed to determine how far inadequacy of diet is reflected in poor physique and impaired health. The tentative conclusion is found that a diet completely adequate for health according to modern standards is reached at an income level above that of half the population. The important aspect of the survey is the inadequacy of the diets of the lower income-groups and the much lower standard of health of the people (especially of the children) in these groups compared with those who have more money.

HISTORICAL COMPARISONS

In 1835 the prices of bread and flour were much the same as they are to-day, but the average consumption per head was 80 per cent. greater. The consumption of sugar was 20 lb. per head, whereas now it is 100. This increase has, of course, been rendered possible by the great fall in price; sugar, which was about 6d. a lb. in 1835, now costs less than half as much.

A committee of the British Association appointed in 1881 gave the first estimates of food consumption. Comparing the figures of 1934 with those estimates, the most striking changes are: consumption per

¹ Food, Health, and Income. Report on a Survey of Adequacy of Diet in relation to Income. By John Boyd Orr. London: Macmillan and Co., Ltd. 1936. Pp. 72. 2s. 6d.

prevention rather than attenuation, especially children under 3 years of age.

According to Kohn and Koiransky, radiological evidence supports the belief that peribronchial infiltration occurs in every case of measles, mild or severe. The frequency with which measles lights up a latent focus of tuberculosis is disputed, but there is no doubt that it occasionally does so and that rapid dissemination may result. Far more important, but as yet not accurately assessed, is the extent to which measles complicated by broncho-pneumonia is the starting point of fibroid lung and bronchiectasis.

E. H. R. HARRIES, M.D., D.P.H.,
Medical Superintendent, North-Eastern
Hospital (L.C.C.).

head of bread and potatoes is 30 per cent. less; of meat 45 per cent. more; of sugar 40 per cent. more; of tea and butter the consumption is double. The same trend of changes is shown by comparison of the figures of 1934 with those of 1909-13 and 1924-28.

METHODS OF INVESTIGATION

To get an idea of the diet in different sections of the community, the whole population was classified, according to the income per head, into six groups; those at the top and bottom consisting of 10 per cent., and the four intermediate groups of 20 per cent. of the population. The composition of these groups was obtained by statistical analysis of a large number of figures, taken from income-tax statistics, wage statistics, and data relating to unemployment, old-age pensions, and other forms of social income. These figures were correlated with a sample taken from the 1931 Population Census and designed to yield information on the sizes of the families and the ratio of earners to dependants in different occupation groups.

The six groups had average incomes per head per week of 10s. and less (group I.), 10-15s., 15-20s., 20-30s., 30-45s., and 45s. and over (group VI.). The corresponding estimated average expenditures on food were 4s. (group I.), rising by 2s. increments to 14s. per head weekly (group VI.). The average income per head was 30s. and the average expenditure on food 9s.

Since the income per head is the income of the family divided by the number of persons supported, an average per head income of (say) 30s. per week may be reached in many ways—for instance, by a skilled worker at £3 per week with only a wife to support, by a worker and his wife both in employment with earnings of 38s. and 22s. per week, or by a man earning £550 per year with a wife, four children, and a maid. This means that any one group will contain a heterogeneous collection of occupations, wage-earners, and non-earners. The poorest 10 per cent. of the population (group I.) consist in the main of families having a disproportionate number of children or other dependants per earner. It is estimated that half the persons in this group are children under 14 and that it contains between 20 and 25 per cent. of the children in the country.

The total food-supply of the country having been estimated, its distribution among the different income groups was estimated from 1152 family budgets. These ranged from very poor families spending less than 2s. per head weekly on food, up to families with an income of £2000 per annum spending 15s. or more per head weekly on food. The composition of the average diet of each group was then examined.

CONSUMPTION OF PARTICULAR FOODS AT DIFFERENT INCOME LEVELS

The consumption of flour (see Fig. 1) and of potatoes is remarkably uniform in all groups except I. and VI. In group VI. there is evidence that more expensive foods are substituted for potatoes and bread. In the lowest group there is no indication of any substitution, nor indeed is there any cheaper food which could be substituted for potatoes and bread. It looks as if the purchasing power of this group is so low that the consumption of even the cheapest foodstuffs is limited; or, what is more probable, the appetite in the lowest income-group is

below the average—one of the first signs of sub-optimal nutrition being diminished appetite.

Graphs published in the report show that as income rises the consumption of margarine falls and of butter rises; but if butter, margarine, lard, suet, and dripping are grouped together the total fat consumption rises steadily with income. The consumption of meat, fish, milk, eggs, sugar, vegetables, and fruit increases with income. The figures for milk, fish, and fruit are shown in Fig. 1.

COMPARISONS OF DIET AND STANDARD REQUIREMENT

The next step is the comparison of the quantities of the constituents in the average diets of each group with the amounts required for health. The standards of requirements adopted are those compiled by Stiebeling, of the United States Government Bureau of Home Economics. The vitamin requirement for health is taken as twice that which will prevent the occurrence of obvious deficiency disease. An ample supply is necessary since it is known that there are minor degrees of ill-health caused by deficiencies of vitamins not great enough to show obvious symptoms. For mineral elements the standards are based on the minimum requirements for the maintenance of a positive balance plus an allowance of 50 per cent. for additional requirements of maintenance of health.

Assuming the validity of the standards, the average diet of group I. is found to be inadequate for perfect health in all the constituents considered. Group II. is adequate only in total proteins and total fat; group III. is adequate in energy value, protein, and fat, but is below standard in minerals and vitamins; group IV. is adequate in iron, phosphorus, and vitamins, but probably below standard in calcium; group V. has ample margin of safety in everything with the possible exception of calcium; in group VI. all standard requirements are exceeded. These results are shown in Fig. 2. The quality of the protein is important, especially for children; and the percentages of protein and fat of animal origin, which are of higher biological value than those of plant origin, increase from group to group. Hence the intake of the several constituents increases in quality and in quantity with expenditure.

It should be kept in view that the standards with which the above comparisons are made are for the maintenance of perfect health, which is a standard

FIG. 2.—Average intake of vitamins and minerals by income-groups. (Modified from the Report.)

very different from the average health of the community. That average diets of the lower income-groups are inadequate according to these standards does not mean that these people are starving or even suffering from such ill-health as is recognised in the term disease. These diets may suffice to maintain life and a certain degree of activity, yet may be inadequate for the maintenance of the fullest degree of health.

EVIDENCE OF IMPERFECT NUTRITION

Owing to differences in their diet, a comparison of the health of children of the lower income-groups with that of children of the higher should show a slower rate of growth and a greater incidence of deficiency diseases in the former. Stature is largely determined by heredity but the extent to which a child will attain the limit set by heredity is affected by diet. Because of these hereditary factors, data which are numerically few are of little value. Ample data on height and weight of the same race do, however, give an indication of the relative adequacy of diets. A conspicuous difference in the heights of boys drawn from different classes is shown by a large number of observations of council schoolboys and employed males (belonging mainly to groups I. to IV.), and those attending Christ's Hospital School (groups III. to VI.). Thus at 13 years of age the boys of Christ's Hospital School are on the average 2.4 inches taller than those of the council schools. At 17 they are 3.8 inches taller than "employed males" of the same age. Figures taken from observations of public schoolboys (belonging

FIG. 1.—Consumption per head of certain foodstuffs by income-groups. The income in Group I. is less than 10s. a week; in Group VI. it is 45s. or over. (Modified from the Report.)

almost entirely to group VI.) show further increase on those for Christ's Hospital.

Three characteristic signs of malnutrition in children—rickets, bad teeth, and anæmia—are fairly widespread in the lower income-groups, the only groups in which extensive observations have been made. There is evidence to show that the same dietary deficiencies which cause these conditions also affect resistance to some infectious diseases, such as pulmonary and intestinal disorders of children.

Such imperfect nutrition in childhood should be traceable as poor physique in adult life and has been found, for instance, in army recruits. Furthermore, susceptibility to some infections, more especially to tuberculosis, is influenced by nutrition and the report states that the most effective line of attack on tuberculosis is probably by improvement of diet.

Figures are insufficient to show the incidence of anæmia in the higher income-groups, but some degree of anæmia is known to be common in women in the lower income groups. This is at least in part preventable and diet is an important factor in its prevention.

The correctness of the general picture presented here has been confirmed by various experiments, in some of which (e.g., Corry Mann) a supplement of milk increased the rate of growth among children. In another, groups of rats kept on diets similar to those of various Indian tribes showed to a remarkable degree the physique and incidence of diseases corresponding to those of the respective tribes (McCarrison). In similar experiments in Scotland, reported in the *Journal of Hygiene* (1935, xxxv., 476), two groups of rats have been given a diet resembling that of income-group I., one group of rats having in addition an abundance of milk and green food. Not only were the rates of growth markedly divergent but the death-rates of the two groups differed conspicuously. The mortality to 140 days of age on the supplemented diet was 11.6 per cent., while for those on the experimental diet the rate was 54.3 per cent. This heavy death-rate was mainly due to epidemic infections to which both groups were equally exposed.

SUMMARY AND CONCLUSION

We reproduce substantially Sir John Orr's concluding statements:—

The food position of the country has been investigated to show the average consumption of the main foodstuffs at different income levels. The standard of food requirements and the standard of health adopted are not the present average but the optimum—i.e., the physiological standard, which, though ideal, is attainable in practice with a national food-supply sufficient to provide a diet adequate for health for any member of the community. The main findings are as follows:

I.—Of an estimated national income of £3750 millions, about £1075 millions are spent on food. This is equivalent to 9s. per head per week.

II.—The consumption of bread and potatoes is practically uniform throughout the different income level groups. Consumption of milk, eggs, fruit, vegetables, meat, and fish rises with income. Thus, in the poorest group the average consumption of milk, including tinned milk, is equivalent to 1.8 pints per head per week; in the wealthiest group 5.5 pints. The poorest group consume 1.5 eggs per head per week; the wealthiest 4.5. The poorest spend 2.4d. on fruit; the wealthiest 1s. 8d.

III.—An examination of the composition of the diets of the different groups shows that the degree of adequacy for health increases as income rises. The average diet of the poorest group, comprising

4½ million people, is, by the standard adopted, deficient in every constituent examined. The second group, comprising 9 million people, is adequate in protein, fat, and carbohydrates, but deficient in all the vitamins and minerals considered. The third group, comprising another 9 million, is deficient in several of the important vitamins and minerals. Complete adequacy is almost reached in group IV. and in the still wealthier groups the diet has a surplus of all constituents considered.

IV.—A review of the state of health of the people of the different groups suggests that, as income increases, disease and death-rate decrease, children grow more quickly, adult stature is greater, and general health and physique improve.

V.—The results of tests on children show that improvement of the diet in the lower groups is accompanied by improvement in health and increased rate of growth, which approximates to that of children in the higher income-groups.

VI.—To make the diet of the poorer groups the same as that of the first group whose diet is adequate for full health (i.e., group IV.) would involve increases in consumption of a number of the more expensive foodstuffs—viz., milk, eggs, butter, fruit, vegetables, and meat—varying from 12 to 25 per cent.

If these findings be accepted as sufficiently accurate to form a working hypothesis, they raise important economic and political problems. Consideration of these is outside the scope of the investigation. It may be pointed out here, however, that one of the main difficulties in dealing with these problems is that they are not within the sphere of any single Department of State. This new knowledge of nutrition, which shows that there can be an enormous improvement in the health and physique of the nation, coming at the same time as the greatly increased powers of producing food, has created an entirely new situation which demands economic statesmanship.

MEDICINE AND THE LAW

The Ruxton Murder Trial

IN his summing-up to the jury at the trial of Dr. Buck Ruxton for murder, Mr. Justice Singleton paid a compliment to the medical witnesses who had been called by the Crown. "Never," he said, "have I seen expert witnesses more careful or more eager not to strain a point against an accused person: there was no evidence to contradict them except by Ruxton himself." Their evidence indeed was vital. Dr. Ruxton's wife and Mary Rogerson, the nurse to his children, were last seen at his house in Lancaster on Sept. 14th; on the 29th dismembered parts of human bodies were found in a ravine at Moffat, Dumfriesshire; there were two heads, and the remains were referred to during the proceedings as body No. 1 and body No. 2, these being alleged to be the remains of Mary Rogerson and Mrs. Ruxton respectively. Dealing with body No. 1 Prof. Glaister, Regius professor of forensic medicine at Glasgow University, described the extent to which tissue and skin had been cut from the face; both eyes had been removed. Asked by the judge if he could see any other reason than the prevention of identification, he observed that the removed parts of the body included those which might have borne signs of asphyxia. The dismemberment had been done by cutting through the joints. There had been bruising before death; blood had been drained away before

it had time to clot. Prof. Glaister put the time between the death and the mutilation as a few hours: he gave 10 to 14 days as the approximate time between death and his examination of the bodies on Oct. 1st, but added that the period could not be scientifically estimated. As for body No. 2 he thought five hours was the minimum time for dismemberment. He found bone changes on the left great toe which frequently accompanied a bunion (there was other evidence that Mrs. Ruxton suffered from a bunion of this nature). He had at first thought that head No. 2 was that of a male: after careful examination and tests he had no personal doubt the head and limbs of No. 2 were those of a female. He described the colour of the hair of the two bodies. Prof. J. G. Brash, professor of anatomy at Edinburgh University, gave his opinion that there were only two bodies and that both were female. He showed that the cast of the left foot of No. 1, on which a stocking was placed, fitted the shoe of Mary Rogerson; similarly that of the left foot of No. 2 fitted the shoe of Mrs. Ruxton. Dr. A. C. W. Hutchinson, dean of the dental school at Edinburgh University, described the state of the teeth in the two skulls; 14 teeth had recently been removed, after or just before death, from head No. 2. Prof. S. Smith, Regius professor of forensic medicine at Edinburgh University, and Dr. W. G. Miller, lecturer in pathology at that University, corroborated details and opinions of the previous witnesses. In addition the officer in charge of the fingerprint department of the Glasgow City Police explained the points of similarity between prints on various articles at the Ruxtons' home and the fingerprints of body No. 1, and between photographs of a palm impression on a table in the house and the left palm of body No. 2.

The rest of the evidence against Dr. Ruxton will be within the recollection of readers of the daily press—his blood-stained clothes, his cut hand, his taking up of the stair carpets, their saturation with blood, the scraping of the walls, the fires in the yard, the locked rooms and the unpleasant smell, the quarrels with his wife and the motive of jealousy, the attempt to persuade witnesses to give untrue evidence as to dates, the sudden disappearance and total silence of the two women, the absence of anyone who saw them leave the house, their omission to take with them any of their clothes or possessions, and the fact that some of the gruesome relics in the ravine were wrapped in a child's garment belonging to the Ruxton nursery. Two other points may be mentioned. Among the remains collected from the ravine were 43 parts, mostly soft parts, which were unassigned to either body: in these was a portion which was taken to be a cyclops eye. Counsel for Dr. Ruxton asked questions apparently suggesting that this might be the sole remaining portion of a human foetus. Dr. Ruxton had at one stage said that Mary Rogerson was pregnant and that she had gone off with Mrs. Ruxton to procure an abortion. Prof. Glaister did not regard this cyclops eye as human. Prof. Brash believed it to be the eye of a pig; had it been human, it would have been the eye of a monstrous foetus. The second point was a question of the admissibility of evidence. Dr. Ruxton stood committed for trial on charges of murdering both his wife and Mary Rogerson; he was actually tried for the murder of his wife only. When evidence was being tendered of Mary Rogerson's clothing, counsel for the defence objected. The Crown contended that the circumstances of Mary Rogerson's death and the identity of one body must materially

assist the identity of the other body. The judge agreed. The issue for the jury was whether or not Dr. Ruxton was proved guilty of the murder of Mrs. Ruxton. If it were the fact that she and Mary Rogerson were both in the house on the evening of Sept. 14th, and thereafter there was evidence that portions of the bodies of both were found in a ravine together, the evidence of the body of Mary Rogerson might be material to the issue. The court would not exclude evidence of her clothing which might be one stage towards identification of her body. The jury must bear in mind that they were inquiring into the death of Mrs. Ruxton only. Admission of the evidence involves the legal subtlety that the presence of remains of Mary Rogerson in the ravine might assist identification of the remains of Mrs. Ruxton in the same place but that no inference must be drawn that the accused, because he had possibly murdered one woman, had probably murdered another. Do juries appreciate these fine distinctions? A like question arose over the direction to the jury recently in *R. v. Waddingham*, where there was a suggestion of the poisoning of Mrs. Baguley though the issue for the jury was the poisoning of her daughter.

Gynæcomasty and Accident

In *Murray v. Northey*, last month at the Surrey assizes, the plaintiff, a young man aged 23 who was employed as a gardener, claimed damages against a motorist. The defendant having admitted negligence, the court had merely to assess the amount of the damages. It was part of the plaintiff's case that enlargement of the mammary gland had developed as a result of the accident. He was knocked off his bicycle a year ago by the defendant's car and was bruised all down the right side from shoulder to ankle; there was a fractured right fibula. Pneumothorax was suspected on the right side but, on examination of X ray photographs, was not established. With regard to the gynæcomasty the plaintiff said that the bruising began to disappear three weeks after the accident; a swelling then begun on the right side of the front of his chest, the place being red, throbbing, and tender. These symptoms subsided fairly soon but during the summer months the swelling slowly increased in size; since October there has been no change in size. Mr. R. M. M. Handfield-Jones, F.R.C.S., giving evidence for the plaintiff, said there was a right-sided development of a normal breast comparable to that of a small virgin female breast at 17 years of age; there was no doubt it was true breast tissue. There appeared to be indisputable evidence that the young man was normal before the accident; his mother and the vicar testified to this. Upon these facts Mr. Handfield-Jones expressed the opinion that the breast development was directly attributable to the injury which had stimulated the breast rudiments. In answer to questions he explained to the court the development of the breasts in both sexes, the abortive effort made by the male breast at puberty, and the known examples of the connexion between trauma and growth. Mr. Russell Howard, F.R.C.S., called as a witness on the other side, described the condition as that of a girl about 12 to 14 years of age. He said he had never known a development of this sort to result from an accident. He did not think that a slight enlargement of the mammary gland in a man of 23 was likely to be so caused. Mr. Justice Finlay accepted Mr. Howard's view and considered that the hypertrophy was a freak of nature which was not due to the accident. Of course there was pain and

suffering as the result of the plaintiff's injuries. The court awarded £300 damages for these.

Dispute over a Locum Tenens

In *Browne-Carthew v. Divecha* at the Westminster county court last month a medical practitioner claimed damages for breach of contract to employ him as locum tenens for the last fortnight of August. He had been engaged through a medical agency and apparently, when he arrived at the house of the defendant doctor for whom he was to act, there was a refusal to let him do the work on the ground that he was too old. The plaintiff was, as a matter of fact, 80 years of age; he asserted that he was nevertheless perfectly fit to do the work required of him. Evidently the court agreed with his assertion; after deducting £3 10s. for board and lodging, the judge awarded him £18 4s. (with costs) as damages for the breaking of the engagement. The judge held that the medical agency was authorised by the defendant doctor to engage a locum tenens, and that the defendant, forming a wrong impression of the plaintiff as a "tottering old man," refused to let him proceed with the contract. There seems to have been some dispute between the defendant and the agency whether the defendant had stipulated for a young man. This did not affect the plaintiff if, as the judge decided, the agency had the defendant's authority to engage him. Doctors who desire to make such a stipulation should remember to make their instructions clear.

Unlawful Use of "Doctor"

The Medical Defence Union does good service to the public as well as to the medical profession when it invokes the law against unregistered practitioners who unlawfully, wilfully, and falsely use the title of doctor, thereby implying that they are registered under the Medical Act. In a prosecution at Brighton last week it was stated that there had been correspondence between the Union and the defendant in September, 1934, when he was calling himself an osteopathic physician and surgeon. He then changed his description to osteopathic practitioner. Last May he described himself as "Doctor" on his notepaper and on the plate outside his premises. The Brighton magistrates fined him £20 with £10 costs.

There may be members of the public who will regard the case as one more instance of professional jealousy and petty persecution. Let it be added then that a detective inspector informed the court that the accused, Francis D. Deacon, aged 57, had been previously convicted for larceny and frauds for which he had been sentenced to two terms of three years' penal servitude and two terms of five years' penal servitude; his last conviction was in July, 1933, when he was sentenced to 12 months' hard labour at Surrey assizes for obtaining credit by fraud. Deacon, said the witness, had often adopted the rôle of doctor in the execution of these frauds. Cases of this kind may persuade laymen that the Medical Act has some modest service to perform for the public in distinguishing the registered from the unregistered practitioner. Since a criminal conviction is a statutory ground for removing a name from the Medical Register, it is all the grosser fraud when a man who has served terms of penal servitude puts "Dr. Deacon" on his notepaper and name-plate.

Illness Supervening upon Accident

In *McCann v. Scottish Coöperative Laundry Ltd.* a woman had an accident to her hand in a steam-presser. She lost a finger and her thumb became stiff

and shrivelled. For a time she received compensation for total incapacity. Presently she became fit for light work and her employers gave her work within her powers at her old wages. She had a permanent partial incapacity, resulting from the accident which occurred in the course of her employment; but she was able to accept her employer's offer of suitable work. Then, as it happened, she was removed to hospital suffering from appendicitis and for six months she was unfit for any work at all. This total incapacity was due to illness entirely unconnected with the accident. Was she entitled to compensation during these six months? Her employers were still offering her light work of a suitable nature, but she was unable to accept the offer. The House of Lords has now decided that the claim to compensation is not satisfied by an offer of work which the workman, through old age or illness, cannot accept. An offer by the employers of work which they know the workman is unable to accept is no better than making no offer at all.

In delivering this judgment of the House of Lords in the workwoman's favour Lord Thankerton found a precedent in *Stowell v. Ellerman Lines* (1923). There an accident made a workman's left hand stiff. Two years later he was found to have total incapacity due to the stiffness and also to hernia, prostate trouble, and old age. This total incapacity could not really be attributed to the accident and the county court judge considered that the total incapacity, due to old age or disease, swallowed up the partial incapacity due to the accident. The Court of Appeal held he was wrong, and the employers had to pay.

PARIS

(FROM OUR OWN CORRESPONDENT)

B C G STATISTICS

THE French Academy of Medicine lives up to its reputation as an international as well as a national forum; and at a recent session two of the principal reports came from abroad. One of them was presented by Dr. Guérin on behalf of Dr. Baudouin, of Montreal, and its subject was eight years' experience of B C G in the province of Quebec. Between June, 1926, and the end of 1934, as many as 5126 children were given B C G. Of these, 582 were living in contact with persons suffering from open or presumably closed tuberculosis, the open cases numbering 249. Serving as controls were 971 children who, though not given B C G, continued to live in tuberculous surroundings, as many as 500 of their tuberculous contacts representing open forms of the disease. All the 1553 children living in tuberculous surroundings were kept under close supervision, and in the calculations of their mortality and morbidity no account was taken of the deaths occurring during the first month of life. Between the ages of one month and seven years the general mortality was 10.3 per cent. for the B C G children and 18.7 per cent. for the controls, the deaths from tuberculosis among the B C G children claiming 2.1 per cent., and among the controls 7 per cent. When account was taken only of the children living in contact with open cases of tuberculosis, it was found that, between the age of one month and seven years, the tuberculosis mortality among the B C G children was only 2.4 per cent., whereas it was 11.1 per cent. among the controls. As for the tuberculosis morbidity among the children in contact with open cases, it was 1.7 per cent. for the B C G children and 6.2 per cent. for the

controls. Dr. Baudouin concludes from these observations that the closer the problem of B C G inoculation is studied, the more evident does its efficacy become.

IS SILICOSIS IN MINERS A DISEASE SUI GENERIS ?

The other foreign report was presented to the Academy by Dr. Rist on behalf of Dr. Vossenaar and Dr. Doubrow, and it concerned miners in Holland. Among 600 miners working as such for more than ten years were 60 who had been employed in the mines for more than 20 years. With only one exception, all these long-term miners possessed radioscopically normal lungs. On the basis of this and other observations, the conclusion is drawn that prolonged work in the dusty atmosphere supposed to generate silicosis does not, as a matter of fact, provoke any clinical or radiological pulmonary sclerosis provided the persons concerned were originally healthy. It is only when chronic pulmonary disease, tuberculosis in particular, has prepared the soil that the lungs may become the seat of disease which in some quarters it is at present fashionable to call silicosis. After presenting this report, Dr. Rist dotted its every *i* and crossed its every *t*, concluding that the problem of silicosis, recently supposed to have been solved, is in reality more obscure than ever. He added that a breach had been made in the wall surrounding the notion that silicosis is a disease sui generis.

RATE-BITE FEVER

A good illustration of the dangers of amateur rat baiting is given by Dr. Louis Ramond in the *Presse Médicale* of March 7th. The rat-baiter in question was a floor-polisher, aged 60, who one morning last December saw a large drain-rat enter his premises uninvited. The floor-polisher pursued his guest with a broom-handle, chasing him till the rat was cornered. In an effort of more or less legitimate self-defence, the rat turned on his pursuer, jumping up and biting his left hand in two places. Having laid out the rat, the floor-polisher made his wounds bleed freely before disinfecting them with chlorinated water. There was practically no local reaction, and the whole incident faded so completely into the background that when the floor-polisher fell ill four days later with high fever and vomiting he did not dream of connecting the rat with his symptoms, and he failed to entertain his doctor with an account of his experiences. So, for many days, his doctor puzzled over such alternative diagnoses as influenza, acute rheumatism, tuberculosis, endocarditis, malaria, typhoid fever, undulant fever, erythema nodosum, syphilis, and measles. It was only when Dr. Ramond was called in to consultation over this case that memories were revived and the necessary clue was given to the correct diagnosis. Apart from the brevity of the incubation period and the almost complete absence of a local reaction, the case was typical enough, with its characteristic rash, the recurrence of bouts of fever punctuated by periods of apyrexia, headache, great general fatigue, and pain in the muscles and joints. Injections of novarsenobenzol were prescribed, and after the third injection had been given, complete apyrexia was achieved. The improvement in other respects was so great that the patient could with confidence anticipate an early return to the polishing of floors. The pity of it was that he was ill for six weeks before a consultant was called in and the correct diagnosis made. Why this delay? Is it that rat-hunters are more diffident about recounting their exploits than lion-hunters?

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

THE HOLMES-ADIE SYNDROME

At the recent meeting of the Medico-Chirurgical Society of Edinburgh, Prof. Edwin Bramwell drew attention to the syndrome in which the pupils do not react to light but show a myotonic contraction on convergence, and in which the tendon-jerks are absent. The condition may affect one or both pupils: the latter are often large, but on maintaining convergence for a period of several seconds they slowly contract to a very small size. Prof. Bramwell emphasised the importance of the syndrome as it is not in any way related to syphilis and is apparently a benign condition. He suggested that, as the cause of the condition is unknown, it should be known as the Holmes-Adie syndrome in recognition of its description by Dr. Gordon Holmes and the late Dr. W. J. Adie.

VOLUNTARY HOSPITALS

Dr. Robert F. Barclay at the annual meeting of the Glasgow Royal Hospital for Sick Children gave some figures. He said there are more than a thousand voluntary hospitals in Great Britain containing 85,000 beds; last year there were 1,250,000 in-patients and 5,500,000 out-patients. The total expenditure and maintenance was about £15,000,000 and the income exceeded that figure by about £1,000,000. In addition, over £3,000,000 was raised for the provision of new buildings and equipment. In the last five years the amount expended on maintenance had increased by £2,500,000. Dr. Barclay submitted that the figures give striking proof of the widespread determination to support voluntary hospitals in the country. He pointed out that, while the local authorities had a duty to see that health services of all kinds are adequate for the needs of the people, it was not their legitimate sphere to use their rating powers to compete with voluntary hospitals. The voluntary hospitals in the west of Scotland, of which there are over fifty, have formed themselves into an association, and he emphasised the importance of the voluntary hospitals in Great Britain being effectively coördinated.

IRELAND

(FROM OUR OWN CORRESPONDENT)

ENFORCED RETIREMENT OF MEDICAL OFFICERS

The Minister for Local Government and Public Health has recently issued a circular to all local authorities suggesting that the normal age for retirement of their various officials should be 65, and that in some cases 60 would be a more suitable age. The circular is intended to cover all officers, professional as well as administrative and clerical, of local authorities. At present in few cases is there any age-limit to the holding of office and all medical officers have been appointed without such limit, and on the understanding that they could not be retired against their will except in case of proved incapacity. Many dispensary medical officers have continued to perform their duties to a much higher age than 65, and in fact the retirement of one at the age of 80 was announced within the last few weeks. There is much to be said against continuance in a strenuous occupation to so advanced an age, but a change cannot be made without a due consideration of existing rights. The Minister has as yet made no statement as to the manner in which he will com-

pensate those whose terms of appointment may be varied without their consent. As the law stands it does not appear that a local authority has power to dismiss an officer on the ground of age alone, but only when it has been proved to the satisfaction of the Minister that there is incapacity to perform the duties. It is true that the Minister has power to remove an officer under sealed order, but up to the present this power has been understood to be exercisable only in cases of rearrangement of duties, of incapacity, or of misconduct, and has not been exercised in other cases.

FEEES FOR REGISTRATION OF BIRTHS AND DEATHS

Most of the work of registration of births and deaths in the Irish Free State is carried out by the

dispensary medical officers, who are appointed assistant registrars for the purpose. It is admitted that the work is performed efficiently and carefully. There has long been discontent as to the adequacy of the fees paid for this work which have not been altered for some eighty years. Representations have been made to successive Governments asking for an adjustment of the fees to modern conditions. Last year the Minister for Local Government and Public Health promised that the matter would have early attention, and last week, in answer to a parliamentary question, his parliamentary secretary stated that the Government draftsman was engaged in the preparation of a Bill to deal with the matter. He was unable to say, however, how soon the Bill might be expected.

PANEL AND CONTRACT PRACTICE

Almost a Representation

THE London medical benefit subcommittee recently submitted a report in which they recommended that a representation should be made to the Minister for the removal of a practitioner's name from the medical list. This action by a subcommittee other than the medical service subcommittee is unusual, but the circumstances attending it are even more extraordinary.

Three doctors, A., B., and C., were involved. By direction of the Minister the name of Dr. A. was removed from the medical list, following a representation by the committee, as from March 1st, 1935. From that date therefore Dr. A. was debarred from taking part in insurance medical practice either as a principal or as a deputy, and his insured patients were given notice of their right to select another doctor.

On Feb. 19th, 1935, the committee were informed by Dr. B. that he proposed to practise at the surgery occupied by Dr. A. as well as at another address in respect of which his name was already included in the medical list. The committee agreed to Dr. B.'s application, subject to the fulfilment of certain conditions, and he accepted a large proportion of the insured persons formerly on the list of Dr. A. Dr. B. relinquished the address as from July 31st, 1935, and nominated Dr. C. as his successor, to whom were transferred the patients attached to the surgery, some 950 persons.

The committee had reason to think that one of the difficulties leading to the retirement of Dr. B. was the continued occupation of the premises by Dr. A., and when Dr. C. joined the list an inquiry was made of him whether Dr. A. was still residing at that address. Dr. C. replied in the negative. On Jan. 29th, 1936, the surgery was visited and the representatives of the committee were then informed by Dr. C. that the practice did not belong to him, and that he was acting merely in the capacity of an assistant to Dr. A. from whom he was receiving a weekly salary. Dr. C. added that he was unable to prevent interference in the practice by Dr. A., and he gave particulars of the case of an insured person who had been attended by Dr. A. and from whom fees had been received. Dr. C. also stated that he had been induced to give a certificate of incapacity to the mother of the insured person although in fact he had not seen the patient at all. Prior to this visit Dr. C. had called at the committee's office and had complained of the conditions under which he was conducting the practice, admitting that his previous statement that Dr. A. did not reside at the surgery was untrue.

The subcommittee's view of the position was that a practitioner (Dr. A.) having been removed from the medical list by order of the Minister of Health was nevertheless still the owner of the insurance medical practice and was continuing to conduct that practice by means of an agent who acted in the capacity of an

assistant and received a weekly salary for his services. This appeared to be nothing less than a travesty of the intention of the Minister when he declared that the continuance of Dr. A. on the medical list would be prejudicial to the medical service of the insured. While no action could be taken against Dr. A. (although doubtless this will be borne in mind in the event of his applying to the Minister for reinclusion in the medical list, for in such circumstances committees are invited to submit their observations on the application) it appeared to the subcommittee that Dr. C. could not be absolved from complicity, and it was the intention to invite the committee to make a representation to the Minister that the continuance of Dr. C. on the medical list would be prejudicial to the efficiency of the medical service of the insured on the grounds that he had conspired and was conspiring with Dr. A. in the conduct of an insurance medical practice contrary to the provisions of the Act.

The chairman of the subcommittee withdrew the recommendation as Dr. C. had resigned from the medical list and the committee were satisfied that his successor had taken the necessary steps to secure that Dr. A. vacated the premises and had no further interest in the practice.

A Complaint that Failed

An insured person complained that an insurance doctor had refused to continue to provide treatment for him. On June 21st, 1935, he applied to the doctor for treatment for a swollen hand, having previously given notice of his desire to transfer to another doctor as from July 1st, 1935. According to the complainant the doctor questioned him as to why he was transferring and suggested he should obtain treatment from the new doctor, to which he replied that he was transferring because he had changed his address but the transfer would not be effective until the end of the quarter. The insured person added that the doctor prescribed ointment but upon being asked whether the patient should attend again said that it was not necessary. The man, thinking that the doctor was off-hand in his manner towards him, assumed that the doctor was not willing to treat him and accordingly consulted the doctor to whom he was going to transfer, paying him 12s. 6d. and incurring further expense amounting to 4s. for dressings. The doctor denied that he told the patient to obtain treatment from the new doctor and said he knew the man was entitled to treatment from him until the end of the quarter, and added that if he had

wanted the patient to go elsewhere for treatment he would have given his consent to an immediate transfer.

The medical service subcommittee thought there had been a misunderstanding on the part of the insured

person and were satisfied that there was no failure on the part of the doctor to comply with the terms of service. The case does however illustrate the embarrassment caused both to doctors and patients by existing arrangements for local transfers.

PUBLIC HEALTH

A New English Life Table

THE series of English life tables begun by William Farr in 1841 has been regularly carried on by his several successors, a new table being constructed at the conclusion of each decade. The latest addition, just published by the Registrar-General, and officially designated English Life Table No. 10, has been constructed by the Government Actuary, Sir Alfred Watson, on the basis of the 1931 census and the mortality experienced in England and Wales in the three years 1930-32. Although the finer points of actuarial practice, as displayed in graduation formulæ for instance, may escape the attention of the public health worker, there can be no doubt that he will find matters of considerable value and interest in the finished product.

EXPECTATION OF LIFE

For example, taking the expectation of life at birth we find that it has increased for males from 40.2 years in 1841, to 51.5 years in 1910-12, 55.6 in 1920-22, and 58.7 in 1930-32, the corresponding figures for females being 42.2, 55.4, 59.6, and 62.9. Thus, at the mortality-rates of 1930-32 the average duration of life from birth for both sexes is a little more than three years above the value given by the death-rates of 1920-22.

It is of some interest to compare the latest values with those of some other countries. Using this expectations of life at birth we find that the present English figures differ inappreciably from those for the white population of the United States, are $2\frac{1}{2}$ - $3\frac{1}{2}$ years better than the corresponding figures for Scotland, but are still 5-6 years below the figures for New Zealand, the country which at present enjoys the highest expectation of life at birth in the world.

The value at birth gives, of course, only a limited view of the mortality experience. Comparing the expectations of life at different ages in England and Wales in 1920-22 with the values in 1930-32 we find that for both sexes the values have increased, by decreasing amounts as age rises, until age 69 is reached in males and age 78 in females. At these advanced ages the average duration of subsequent life is now rather less than it was in 1920-22 or in 1910-12. It is possible that this deterioration can be explained in terms of the survival of the fittest, that there is a survival to old age in the present generation of weaker members of the community who under the conditions prevailing in the past would have succumbed before old age was reached.

VITALITY OF MARRIED WOMEN

In addition to the National Tables the Government Actuary has calculated a valuable series of sectional tables, by means of which the rates of mortality of females according to marital condition can be compared as well as different sections of the country one with another. The most striking feature in the former investigation is the increase at the younger adult ages in the vitality of married women as compared with single women. Although the

maternal mortality-rate (ratio of deaths assigned to childbirth to total births) has slightly increased, the large reduction in the number of births in recent years has led to a smaller total of deaths from puerperal causes. The reduction in the birth-rate has thereby diminished the rate of mortality among married women at the child-bearing ages.

A comparison of the county boroughs of Durham and Northumberland with the rural districts of the east of England also gives very striking results. Out of every 1000 boys born in the former 96 fail to survive the first year of life compared with only 57 in the latter; of 1000 girls 73 fail to survive in the former and only 45 in the latter. At age 50 the number out of 1000 males who fail to survive to age 60 is in England and Wales 149, in the county boroughs of Durham and Northumberland 165, and in the eastern rural districts 100 only, the corresponding numbers for females being 111, 125, and 97.

HEALTHINESS OF THE OUTER RING

Finally, a special investigation has been made of the mortality of Greater London divided into its two constituent sections (1) London administrative county and (2) the outer ring. The figures indicate the superiority of the mortality experience of the latter over that of the former. Comparison of the London suburban areas with other urban areas in the country as a whole shows that the outer ring of London is conspicuous for the lightness of its death-rates over the whole span of life.

This volume, it will be clear, carries on most effectively the long and honourable line of English life tables.

Medical Members of L.C.C. Committees

The London County Council last Tuesday re-elected Lord Snell as chairman for the ensuing year, and on the recommendation of the general purposes committee approved (amongst others) the names of a number of medical members to serve on various standing committees:

Establishment: Miss E. Rickards, F.R.C.S.

Hospitals and Medical Services: Dr. C. W. Brook, Dr. S. Monckton Copeman, Mr. Somerville Hastings, F.R.C.S., Dr. S. W. Jeger, Dr. F. Barrie Lambert, Miss Rickards, and Dr. Henry Robinson.

Housing and Public Health: Dr. J. A. Gillison.

Mental Hospitals: Dr. Robinson.

Parliamentary: Dr. Bernard Homa and Dr. Jeger.

Public Assistance: Dr. Barrie Lambert.

Public Control: Dr. Homa.

In addition to these Dr. Sophia Jevons was co-opted on the Education Committee; Dr. H. L. Eason and Mr. R. H. P. Orde, Secretary of the British Hospitals Association, on the Hospitals Committee.

Medicine is thus thinly but well represented over the various fields of the Council's activities.

CUMBERLAND INFIRMARY.—Presiding at the annual meeting of this hospital the Bishop of Carlisle spoke of the heavy expense involved by motor and accident cases. During the year their cost to the hospital was £888, of which only about £379 had been recovered.

OBITUARY

JOHN SCOTT HALDANE, C.H., F.R.S.

THE death on Sunday last of Prof. J. S. Haldane in his 76th year ends the life and work of one of the greatest—perhaps the greatest—of modern physiologists who for practically half a century has been continuously producing work and thought of the highest order in a great diversity of fields.

In Edinburgh, where he was born and brought up, Haldane began as a philosopher and philosophy remained a lasting interest with him and explains a good deal of what he did and said in later life. His discoveries were made by thinking out what ought to happen and he generally made experiments simply to verify suspicions or conclusions at which he had already arrived; for experimentation to see what

would happen he had little use. And yet, while laboratory work was a relatively minor thing in his life, he is best known to the general run of workers in medical schools nowadays as the originator of incomparably simple and accurate technical methods; the hæmoglobinometer came from an interest in the oxygen-carrying power of the blood, the gas analysis apparatus from an inquiry into deaths after explosions and fires in mines, the alveolar air method of determining the

PROF. HALDANE

(Photograph by Russell)

condition of the respiratory centre from meditation on what probably regulated ordinary respiration. And these three examples explain too the position he held among such diverse people as clinical pathologists, mining engineers, and physiologists: to anything with which he concerned himself, he made additions of knowledge which put him in the front rank. Breathing was perhaps his greatest interest, and he has fortunately left behind him an adequate monument in his "Respiration," Silliman lectures of 20 years ago of which his wonderful vitality allowed him to write a new—really new—edition long after he was 70. In this he covers normal and abnormal breathing as well as other topics which he had illuminated—carbon monoxide poisoning, mountain sickness, and work in compressed air. His interest in mining led him on to some pioneer work on silicosis, the discovery of ankylostomiasis in Cornwall, and the examination of the effect of high temperatures which has more recently matured into an explanation of miners' cramps by salt depletion. Not long ago he surprised us with some striking experiments on colour vision which recalls an earlier interest in the twinkling of stars.

The versatility of which these are but instances—a catalogue would be far too long—was not the product of a volatile mind which is about the last thing of which anyone who knew Haldane would suspect him. For most physiologists, the theme which

holds their various inquiries together is departmental—an interest in the circulation or the central nervous system, sometimes even a liking for some technique. With Haldane, the principle which made all his work coherent was a passion for a philosophical physiology on which he often wrote and lectured: any physiological subject would do to illustrate his general faith. What exactly this was it was often difficult to understand and as was only natural his views went through an evolution and development as his thought and experience progressed. But throughout he had an implacable disbelief in the possibility of explaining what animals did by any available system of chemistry and physics. At first he argued on such things as the apparent secretion of oxygen by the lungs, at any rate in times of stress. Later he attached less importance to the nature of the mechanisms and laid more stress on the ideas that the body works as a whole, and as a whole which is something more than its parts, that organisms cannot be detached from their environments and that their responses follow no hard-and-fast line without respect to circumstances. These views are fairly intelligible to anyone, and his constant insistence that physiology must be looked at in this kind of way has permeated much of the modern work and produced a change of view which has to be seen historically to be appreciated: Haldane's general influence in this way has probably been as important as the special impression which he made on the topics which he took up in detail. Finally he expresses himself as convinced of the necessity of a spiritual interpretation of biology with God as the final reality, a point of view which is perhaps difficult to pass on to anyone who has not felt it for themselves. Haldane's whole career is proof that he found such an outlook a most profitable basis for effective research of all kinds: those who would like to know more of it would do best to read the volume of essays and addresses called "Materialism," and they may be less bewildered than the lady who went to hear one of his Gifford lectures in Glasgow and on being asked how she liked it said "Well enough, though I was a bit disappointed: I thought it was to be about God and he talked about nothing but kidneys": to Haldane the connexion would be clear enough.

Haldane was also a great personality—one of those men who go about with an aura—and those who were lucky enough to be among his pupils at Oxford will know what a pity it is that he had not done any undergraduate teaching for more than 20 years. And yet his freedom from the cares of routine gave him time and opportunity for his wonderful output and there are many graduate students who are profoundly in his debt. Kindly, courteous, considerate, he did not suffer fools gladly, and he was apt to be a little impatient with criticism. There was indeed seldom much room for it.

JAMES RUTHERFORD, L.R.C.P. Edin.,
F.R.F.P.S. Glasg.

Dr. James Rutherford was born in Kirkmichael in 1858, the son of Robert Rutherford, a distinguished Greek and Hebrew scholar. He received his medical training at Anderson's and St. Mungo's Colleges, and at the latter institution was medallist in clinical medicine. He gained his first diplomas in 1894 and served as house physician at the Royal Infirmary, Glasgow. Later he went into practice at Harrogate

where he had a large connexion and also took a prominent part in municipal politics, serving as deputy-mayor of the town during the war. In 1926 he was elected F.R.F.P.S. Glasg. Dr. Rutherford married Amy Eleanor, daughter of Mr. R. Hyde-Parker, of the Wesley College, Sheffield, and was the father of three prominent Harrogate practitioners, Dr. Raphael Rutherford and Mr. Eric Rutherford, who succeed him in his practice, and Dr. Kathleen Rutherford, who is also a practitioner in the town.

THOMAS BABINGTON GRIMSDALE, M.B. Camb.

HONORARY GYNÆCOLOGICAL SURGEON, LIVERPOOL ROYAL INFIRMARY

Thomas Babington Grimsdale, who died suddenly at Seaton, Devon, on March 11th, was the son of Dr. Thomas Frederick Grimsdale, a widely known physician and gynæcologist in Liverpool. He was educated at Uppingham and Trinity College, Cambridge, proceeding to St. George's Hospital for his medical training. At the hospital he was assistant medical registrar and assistant house physician, and graduating as M.B. Camb. in 1883 returned to Liverpool, where he practised with success as a gynæcological surgeon for nearly 40 years.

His first appointments in Liverpool were as assistant medical officer to the Liverpool Hospital for Women and the Liverpool Infirmary for Children, and he was shortly elected to the staff of the Liverpool Royal Infirmary as gynæcological surgeon. The fame of the father and Grimsdale's own merits soon secured for him a high position and a large practice, but just after his appointment to the Royal Infirmary he entered upon a struggle, the recollection of which still remains. It is thus described by "W. M. C.": "Convinced from observation of the work of others and the results of his own experience that aseptic methods should supersede those of the older antiseptic practice, Grimsdale set himself zealously to have the new take the place of the old. In this endeavour he was strongly opposed by certain of his senior colleagues, notably by one who had the ear of the then committee. New-fangled ideas, especially when they involved considerable expense, did not find favour and for a time it seemed that the suggested new enterprise must go to the wall. But Grimsdale, strong in the right of his cause, kept fighting on, an unremitting fight against continued opposition from above, until he won on every point and was successful in getting the new régime established. What is now taken as a matter of course involved the pioneers in a struggle against prejudice almost unbelievable. It is gratifying to be able to record that eventually the chief opponent admitted with all chivalry that Grimsdale had been right."

In the medical school Grimsdale was a successful clinical lecturer and in his contributions to the North of England Obstetrical and Gynæcological Society—of which he became president—and in his communications to the *Liverpool Medico-Chirurgical Journal* he showed his practical knowledge of his subjects. He wrote only occasionally but always delivered a practical message. In his practice he was noted for his scrupulous attention to detail, while he was a very skilful operator. When the war broke out Grimsdale, who had been an acting surgeon in the 4th Lancashire Volunteer Artillery, was too old to go abroad, but he gave valuable surgical help to the St. John Ambulance Brigade V.A.D. Hospital in Liverpool, coming to the assistance of the heavily overworked surgeon to the hospital, the late Mr. G. P.

Newbolt. He retired from the staff of the Royal Infirmary in 1921 being made honorary consulting gynæcological surgeon to the Infirmary, and for the remainder of his life lived in the South of England.

Dr. Grimsdale married Helen, daughter of Mr. Henry Jevons, but had no family. His younger brother, Dr. Harold Grimsdale, is consulting ophthalmic surgeon to St. George's Hospital.

W. M. C. further writes: "By the death of T. B. Grimsdale a long and eminent family medical connexion with our city of Liverpool comes to an end—a connexion dating from 1848 when his father Dr. T. F. Grimsdale began a brilliant career. T. B. Grimsdale, who followed his father in residence at 29, Rodney-street—a Grimsdale home since 1862—would describe himself as the oldest inhabitant of Rodney-street, a thoroughfare of medical renown in the city. He succeeded his father as gynæcological surgeon first on the staff of the Liverpool Hospital for Women and later on that of the Royal Infirmary. The family was a gifted one, and T. B. Grimsdale inherited considerable artistic talent which he exhibited on occasion in the sketches which it was his habit to make of his fellow guests at public dinners during post-prandial eloquence. In his professional work he was meticulous to the last degree, not tolerating carelessness on the part of his coöperators, whether doctors or nurses, while to assist him in his operative work was an education in the technique of abdominal surgery. I often had this privilege and have often felt that I never did so but I learned something in the minutiae of technique. In his time he was an active sportsman. As a cricketer he made occasional appearances in the Lancashire county eleven, while he was captain of his golf club. After retirement he became devoted to fishing."

ERNEST HARRISON GRIFFIN, D.S.O., M.C., M.R.C.S. Eng.

THE death occurred on March 10th of Dr. Ernest Griffin, to the regret of a large number of patients and friends acquired in the course of an interesting and adventurous career.

Ernest Harrison Griffin was born at Walsall in 1877 where his father was connected with the *Walsall Observer*. He was educated at Queen Mary's School, Walsall, and entered Peterhouse, Cambridge, as an undergraduate in 1895 where he graduated in arts. He proceeded to Guy's Hospital as a medical student and did some post-graduate work in Paris. He obtained the L.S.A. diploma but did not proceed to medical graduation, commencing at once his picturesque career. He took a post as medical officer in the Venezuelan Rio del Oro Goldfields Company and was for a time surgeon to the El Dorado Gold-mining Company. He received in Venezuela the Order of the Liberator. On his return to England he developed an interest in psychological medicine and for a time acted as assistant physician and pathologist to the Camberwell House Asylum. He also gained the diploma at Cambridge of D.T.M. and Hy. But he had a veritable spirit for adventure and he became surgeon to the Red Crescent Society in the Italo-Turkish war of 1911. In Tripoli he saw very much fighting in a campaign complete with the incidents of guerrilla warfare and was seriously wounded and left on the battlefield for dead. He was, however, rescued, and the recollection of the courage and devotion of his Turkish comrades was always vivid with him. His brief work "Letters of

a Wanderer," written in 1913, deals with many exciting experiences of which he later gave more in a volume entitled "Adventures in Tripoli."

Taking up his life again in England he held the post of resident medical officer to the French Hospital, where he had once been a clinical assistant, but he joined up on the outbreak of the European War as a temporary captain in the R.A.M.C. He soon became conspicuous for his devotion to duty and his remarkable courage. He was wounded several times and thrice mentioned in dispatches; was awarded the M.C. and bar and received the D.S.O. for conspicuous gallantry, the occasion being thus described in the *Gazette* :—

DR. GRIFFIN

[Photograph by Swaine

"He established his dressing station well forward during an attack, and went up to the front line through a storm of artillery and machine-gun fire utterly regardless of personal safety. He moved about in the open for 36 hours without food or rest, attending to the wounded, often leading parties of bearers through heavy barrages until every wounded man had been carried back. He remained behind after the battalion was relieved, still searching for wounded, under heavy fire, though he was several times badly shaken by the explosion of shells."

In 1918 he was reported dead as he had been reported nine years before in the Italo-Turkish war. This occurred during the last great German offensive, when he was found on the battlefield by the Germans to be still alive. In the war hospital he was recognised by the Turkish ambassador through whose representations his release was obtained, and he returned to England, with his health seriously damaged by his terrible experiences, though he remained at work as a specialist in venereal diseases with the Aldershot command.

At the conclusion of hostilities he picked up the threads of his academic career, graduated M.A. at Cambridge, took the English double diploma, and started in practice in Upper Berkeley-street, specialising in medico-physics. He met with considerable success; his interesting personality counted here, while his outspokenness secured confidence and he had thoroughly equipped himself. He always retained his deep interest in Turkey. He became honorary secretary of the British Red Crescent Society and medical officer to the Ottoman Embassy. He was the main founder of the Near and Middle East Association, and was prominent in the development of a body that has done much to shed public light upon many serious political and racial difficulties in Asia Minor and Palestine. He was unmarried.

SIDNEY HERBERT CLARKE, M.D. Camb.

Dr. Sidney Herbert Clarke, who died on March 5th, was the son of the late Dr. J. St. T. Clarke and was educated at Oakham and Gonville and Caius College, Cambridge. He proceeded for his medical education to the London Hospital and graduated as M.B.,

B.C. Camb. in 1905. His first direction of practice was in psychiatry, and he was assistant medical officer to the Leicester and Rutland Asylum, the Newport Borough Asylum, and the County Asylum, Prestwich. In 1909 he obtained the M.D. degree and later commenced practice in St. Albans, being at the time of his death surgeon to the St. Albans and Mid-Herts Hospital, and honorary secretary of the Hertfordshire Medical and Panel Committee.

ROBERT RENDLE LEATHAM, M.B. R.U.I.

CONSULTING PHYSICIAN, BELFAST HOSPITAL FOR SICK CHILDREN

Dr. Robert Leatham, who died recently at his home, Mountnorris, Newcastle, Co. Down, was educated at the Royal Academical Institution, Belfast, and entered the Queen's College as Pakenham Scholar. He graduated in arts with first-class honours in 1889, won the Dunville Studentship two years later, and qualified M.B., B.Ch., B.A.O. with honours in 1893. After holding various resident hospital appointments he commenced practice in Belfast. From the first he took a special interest in children and quickly won their confidence and affection. He loved his work as physician at the Belfast Hospital for Sick Children. His lectures attracted large numbers of students to the hospital for his clinical teaching was always arresting, lucid, and practical, illustrated from his rich clinical experience and his wide knowledge of the literature of pædiatrics. Possessing a logical and analytical mind, he studied each patient with absorption both from a physical and psychological standpoint. The words of Trousseau were true for Leatham—"Il n'y a pas de maladies : il n'y a que des malades." He gave to his patients of his very best, no matter what the giving cost him in nervous energy and physical strength. Thirty years of concentrated work told on a frame never robust, and taking heed to certain subjective cardiac warnings he retired from practice some years ago.

A friend writes: "All though Leatham's life beauty—in nature, in art, in literature, in architecture—had struck a responsive chord in him. On his retirement, still in his prime, he was fortunate in being able to surround himself with the beautiful things he loved. His home, which lay on the foothills of the Mourne Mountains, was surrounded by a garden which at every season of the year was lovely, and his home was filled with beautiful things, furniture and pictures, for he was a connoisseur and a keen and gifted collector. His interest in the Children's Hospital never waned. Ceaselessly he urged the board of management to leave their cramped quarters in the heart of the city and to build a modern hospital in the open space facing the Antrim Hills available close by the Royal Victoria Hospital. Having carried this point he threw himself with enthusiasm and thoroughness into the consideration of plans, and the new Children's Hospital embodies many of his ideas. To-day it stands a permanent memorial to his courage, faith, and generosity."

MEDICAL CONGRESSES AT WIESBADEN.—Owing to the Reichstag election the various congresses arranged to be held at Wiesbaden in the last week in March have been postponed. The Gesellschaft für innere Medizin will meet from April 20th to 23rd, the Röntgen Gesellschaft from April 23rd to 25th; and from April 18th to 20th will meet the Reichsarbeitsgemeinschaft für eine Neue Deutsche Heilkunde. Room reservations are now to be sent to the Städtische Kurverwaltung, Wiesbaden, Germany.

CORRESPONDENCE

THE NUTRITION QUESTION

To the Editor of THE LANCET

SIR,—May I reply to Dr. Hutchison's contention that practitioners in touch with the poorer classes would deny the existence of widespread malnutrition? In assessing malnutrition we are bound to get a great divergence of opinion, as the term is ill-defined. It is also unsatisfactory as it is an aetiological definition. If in its place we substitute the term "unsatisfactory physique," and give this as specific a meaning as we can, we are on safer ground. By unsatisfactory physique I mean a child (I am confining myself here to discussing children) who is below weight, generally below average height, thin, with poor muscle tone and poor posture, who is pale, whose mucous membranes are pale, and who has baggy eyes and a tired look. Such children look prematurely old. I recently found some 70 such cases amongst 240 boys in a poor East End district.

Dr. Hutchison contends that sheer poverty is not a cause of malnutrition. Be that as it may, I think the following figures in connexion with the "unsatisfactory physique" may be of interest. In the course of an investigation, I had occasion to compare two groups of 40 East End children. One group was especially picked to contain only children of the best physique. The other consisted of the type of child described above. In the "good" group, "poor circumstances" (meaning long spells of unemployment, irregular work, or disablement of the father during the child's life) were present in 6 cases; in the "bad" group, poor circumstances occurred in 26. In the "good" group there was only 1 case where the parent declared that at any time during the child's life it had been short of food; in the "poor" group this history was elicited eight times. Parents give notoriously bad histories, but chance alone would not give such a difference. Moreover parents who think their children have not had enough to eat look upon this as a reflection upon themselves, and it needs close questioning to elicit such an admission. Then the most one gets is an answer such as "Well he didn't get all we should have liked him to." This means the child may have had only two meals a day. In bad times it appears that the diet contains little besides potatoes, greens, meat on alternate days, porridge and bread and margarine for breakfast, and for supper tea with some milk and bread and jam.

A number of parents have told me they have gone short themselves to feed their children. The average wage of a family is about £2 5s. a week—seven living on £2 10s. and one case of three on 22s. a week—9s. rent are a few cases that come to my mind. Such cases certainly appear to avoid the dangers of over-nutrition against which Dr. Hutchison warns us!

Obviously other factors such as overcrowding and nervousness play a part. Again, if I may further quote my own figures, 7 cases of nervousness occurred in the "good" group, 13 in the "bad" one, where conditions dependent on poverty predominated.

I submit that it is very important that we should not allow a discussion on malnutrition to become academic because of difficulty in defining the term, or because of prejudices which may have become attached to the word. What is essential to realise is that an enormous number of working-class children are in an unsatisfactory condition compared to those

of the well-to-do classes, and that their condition is due to factors associated with poverty.

I am, Sir, yours faithfully,

W. L. NEUSTATER.

Devonshire-place, W., March 14th

PROGNOSIS IN SPINAL CARIES

To the Editor of THE LANCET

SIR,—I have read with interest Mr. Persy Fisher's kindly criticism of the statistics in my article and hasten to reply. Mr. Fisher has misread the figures. I did deal with only those cases in which a conclusion had been reached, which is exactly what he advocates. The figures then are—

Total cases the outcome of which is known	..	1582
Of these there died	61
Percentage of deaths	3.8

Of the total number of cases admitted (1666) 84 remained under treatment on March 31st, 1935; these do not count for mortality statistics as treatment was not concluded. The error in the causes of death is accounted for in this way: In the causes of death it was stated that 16 children (1.01 per cent.) had died of sepsis and amyloid disease, but in the following table 15 were stated to have died of that condition and 14 other causes. The discrepancy was due to the fact that one of the patients, a child with a tuberculous spine, had a non-tuberculous empyema, which was the cause of death. She was septic and amyloid but death was not due to tubercle and so was entered under "Other causes."

I am, Sir, yours faithfully,

March 16th.

HENRY GAUVAIN.

INTRAVENOUS ANÆSTHESIA FOR
CHILDBIRTH IN A MENTAL HOSPITAL

To the Editor of THE LANCET

SIR,—The care of a pregnant psychotic patient presents a series of problems for which there is no authoritative solution. In spite of the supposed stigma to the coming child it is generally agreed that the primary consideration is the proper treatment of grave mental illness. Antenatal care must be more than usually thorough, since psychotic patients seldom reveal the early symptoms of toxæmia. Special difficulties occur in the diagnosis and management of labour. There is a real danger of depressed or stuporose patients passing quietly and unnoticed through all the stages of labour, and this risk can be avoided only by frequent examinations and careful observation as the patient approaches term. The actual management of labour involves exceptional risks, including violence and a tendency to excessive uterine action. These risks can be avoided by means of continuous anæsthesia. The method of choice is intravenous anæsthesia with Evipan or Pentothal.

Pentothal sodium 1 g. is dissolved in 10 c.cm. redistilled water. Intravenous injection is begun at the onset of strong and regular labour pains. The initial dose of 2 c.cm. is followed a minute later by a further 2 c.cm. The patient is now unconscious and the syringe can be fastened to the forearm. Labour is unaffected but the patient becomes increasingly suggestible and amenable. Gradual emergence from this twilight state is an indication for a further 1 c.cm. This degree of narcosis is conducive to adequate coöperation during the second stage of labour. Repeated injections of 1 c.cm. may be given as often as required, and the twilight state can be deepened into surgical anæsthesia by injecting a further 3 c.cm. This is invaluable

for the performance of obstetric operations or perineal repairs.

At the end of labour it is convenient to inject ergometrine intravenously before removing the syringe. The recovery-rate is very quick and unaccompanied by restlessness. A last and most important observation is that there is no apparent ill-effect on the child. This technique is on the lines suggested recently in your columns by Dr. Jarman and Mr. Abel (*THE LANCET*, Feb. 22nd, p. 422, and March 14th, p. 600).

I am, Sir, yours faithfully,
Dorchester, March 14th. STEPHEN HORSLEY.

PRURITUS OF THE VULVA AND ANUS

To the Editor of *THE LANCET*

SIR,—The causes of the above conditions which are enumerated in the interesting article by Dr. Elizabeth Hunt in your last issue differ widely from those which I see in private practice. In 1929, at your request, I wrote on the treatment of these maladies, and subsequent experience confirms my opinion that the chief cause of vulvar pruritus is a discharge from the vagina, cervix, or uterus. Perhaps it is because gynaecological cases are sent to me for treatment with local ionisation or diathermy that a discharge forms so high a causal proportion among my list of cases of vulvar pruritus and eczema. The most irritating of such discharges is usually due to *B. coli* infection, and when this is accompanied by faecal streptococci the pruritus soon becomes eczematous. Next in order comes *B. coli* urinary infection, and an eruption which I label (perhaps wrongly) streptococcal dermatitis; this may be the rash which others call seborrhœic dermatitis. It shows a vivid erythema on and round the vulva, whilst the thighs, groins, and lower abdomen are covered with small round or ovoid patches, slightly scaly at their edges; where these join the eruption has a circinate margin. On staining the scales no bottle bacilli are seen, nor fungi, but only cocci. Later fissures and weeping develop; the condition responds to the treatment for streptococcal dermatitis. Sometimes this rash follows a vaginal discharge, but quite as often it arises without apparent cause. Tight combinations, with thick folds, especially in winter, appear in some cases to set up this rash. Other causes are friction and perspiration, especially in summer, in stout women, and tight clothing which is contaminated with urine and faeces. Fungal infection was often seen after the war, but of recent years, although it appears to be as common on the feet, I have not seen so many cases of vulvar infection due to this source. Leucoplakia, lichen planus, and diabetes figure rarely in my list of cases. I saw one case of leucoplakia clear up when unnecessary vaginal douches were stopped; but the very next case which came my way soon developed malignant disease, and neither radium nor surgery could avert a fatal issue. Hence, when these cases do not immediately respond to soothing remedies I prefer to send them to a surgeon. Kraurosis in elderly women, on the other hand, usually answers to diathermy with surprising success. I have comparatively recently become aware of another cause of relapsing irritation—namely, *B. coli* infection of the urethra.

As regards the anus, the chief cause of pruritus appears to be extension from streptococcal vulvar infection, paraffin leakage, mucous leakage in association with hæmorrhoids, and threadworms. I am always glad I heard the masterly address by Colonel MacArthur to the British Medical Association at

Eastbourne on this subject. Since then I have found several cases of severe, extensive eczema of the anogenital region, which had been cured more than once and relapsed at varying intervals of time, clear up rapidly and for good when treatment was focused on the threadworms.

I am, Sir, yours faithfully,
Devonshire-place, W., March 16th. AGNES SAVILL.

TREATMENT OF VAGINAL DISCHARGE

To the Editor of *THE LANCET*

SIR,—It has been my experience in Germany that leading professors of gynaecology and obstetrics, as masters of the scalpel and the X rays, sometimes do not take much interest in vaginal discharge and leave the treatment of this minor malady to their assistants. Progress in this field is therefore slow.

The pharmacological industry has produced a great many preparations for treating the condition and Devegan is one of the newest and best recommended of these. A remedy for vaginal discharge, however, has often to be applied for weeks and even months, so that expensive drugs have to be abandoned as the cost becomes too high. I have therefore tried to find a cheaper preparation. I read that Prof. C. J. Gauss, of Würzburg, was recommending Vagintus, a granulated form of aluminium acetate. The salt, which in Germany costs only about 5s. per lb., should be procurable from any chemical manufacturer. But it must be in *granulated* form; the ordinary powder would clot together. Before using it the vagina and cervix is lightly cleaned, through a speculum, with cotton-wool and hydrogen peroxide to remove the alkaline mucus. A teaspoonful of the acetate is placed near the cervix and the vagina is closed with a dry tampon, which the patient removes some hours later. This is done twice a week. If it is convenient for the patient to attend, boric acid powder is introduced on the other days in the same way. The treatment has remarkable effects even after the first application, and nearly always at the second attendance the patients appear happy and pleased at the sudden disappearance of an evil-smelling discharge.

The advantages of the dry aluminium acetate powder treatment are: (1) the remedy is extremely cheap; (2) it has an immediate effect, giving confidence to a patient sometimes in despair through having the discharge for years; (3) it is based on the physiological principle that the reaction of the healthy vagina must be acid. It produces twice or three times a week a strong acid reaction, lasting many hours from the big quantity introduced; and nature generally finds a way to restore the normal healthy flora formed by Döderlein's bacillus of acidum lacticum.

I agree with Mr. Gordon Luker that we have to consider endocervitis or even salpingitis as a common cause of discharge but, in practice, even the most skilful gynaecologists cannot arrive quickly at this diagnosis. I am well acquainted with the American literature of my specialty and I know how many methods, especially that of electrocauterisation of the cervix, have been advocated by them; but all are complicated and give the patient the impression that her condition is serious. In Prof. Gauss's opinion, if we merely cleanse the vagina and produce an acid reaction, the self-helping and self-healing forces of nature may also heal an endocervitis. *Medicus curat, natura sanat.*

I am, Sir, yours faithfully,
London, March 17th. R. KUHN.

A QUESTION OF PROFESSIONAL CONFIDENCE

To the Editor of THE LANCET

SIR,—Particulars of a recent tragedy may serve as a warning to more than one section of your readers. A is a practitioner attending a family in which B is a general servant. B develops what A thinks is an "acute abdomen" and is sent into hospital for operative treatment. In hospital B is found to be suffering from gonococcal salpingitis not requiring operation and is transferred to the "V.D." ward. While in this ward B is visited on the ordinary visiting day by A who, without permission and in the presence of the nurse, takes down and reads the case record on the bed-card. Two days later, and while still in bed in the ward, B receives notice of dismissal from her mistress who is A's patient. B, whose previous record is highly creditable, is now contemplating suicide. I should like to know what my fellow practitioners think of A's action. It is important to add that B is still on his panel.

I am, Sir, yours faithfully,

March 1st.

IATROS.

* * * The case raises medico-legal issues that are repeatedly cropping up in practice. We think A's conduct cannot be defended, because (1) he made use without permission of case records belonging to the hospital; (2) information might be contained in these records which B did not desire to disclose to A; (3) if A communicated to B's mistress (presumably without B's knowledge and consent) information which led to the notice of dismissal two days after his visit to the hospital, A committed a serious breach of professional confidence; (4) if the dismissal was the result of information conveyed by A as to the nature of B's illness, his conduct must be held responsible for the nervous upset made manifest by B's threatened suicide. The fact that B's previous record was "highly creditable" suggests an inquiry whether the diagnosis of gonococcal salpingitis was correct. Was the gonococcus identified in the discharge from the cervix? Was a cultivation made? If not, the precise nature of the salpingitis could hardly be determined unless the tubes were inspected and examined under the microscope. Tuberculous salpingitis may occasionally be acute, or, what is more common, salpingitis may complicate appendicular or colonic inflammation. Infection from contraceptive appliances must also be excluded before assuming a venereal infection. On the other hand, if the diagnosis were correct it is the business of the hospital to make sure that B is treated until she is no longer a possible source of infection, when she could have resumed her employment.—ED. L.

STAMMERING

To the Editor of THE LANCET

SIR,—Miss Kate Emil-Behnke and her family have contributed so much to the literature and analysis of the technique of speech that I am not prepared to argue with her, but she seemed to me to advocate the use of elocution and, in almost the same breath, to say that it was useless. As a self-cured stammerer long before I undertook the cure of other stammerers I believe that the coördination of all the muscles concerned in speech—that is, true elocution—will correct stammering, which is first of all due to unbalanced speech or lack of coördination. From personal experience I know the confidence

which results from a full understanding of the mechanism of speech.

I am, Sir, yours faithfully,

H. ST. JOHN RUMSEY, M.A.,
Speech Therapist, Guy's Hospital.

March 16th.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
MARCH 7TH, 1936

Notifications.—The following cases of infectious disease were notified during the week: Small-pox 0, scarlet fever 2491, diphtheria 1162, enteric fever 28, acute pneumonia (primary or influenzal) 1431, puerperal fever 44, puerperal pyrexia 152, cerebrospinal fever 26, acute poliomyelitis 3, encephalitis lethargica 6, dysentery 49, ophthalmia neonatorum 86. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on March 13th was 3656, which included: Scarlet fever, 973; diphtheria, 1069; measles, 2138; whooping-cough, 729; puerperal fever, 17 mothers (plus 11 babies); encephalitis lethargica, 283; poliomyelitis, 4. At St. Margaret's Hospital there were 23 babies (plus 15 mothers) with ophthalmia neonatorum.

It will be noted that the number of cases of measles now hospitalised in London amounts to 2183, which is 409 more than last week, and is evidence of the rapid spread of the epidemic of measles in the county.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 3 (0) from enteric fever, 84 (22) from measles, 3 (1) from scarlet fever, 37 (9) from whooping-cough, 41 (1) from diphtheria, 64 (20) from diarrhoea and enteritis under two years, and 112 (28) from influenza. The figures in parentheses are those for London itself.

It will be noticed that the mortality from measles is rising, although not rapidly, the figures for the last six weeks (working backwards) being 84, 88, 78, 58, 34, 41 for the country as a whole and 47, 38, 18, 14, 13, 9 for Greater London. There is a corresponding or even larger rise in the number of cases for which hospital treatment has been sought at L.C.C. hospitals. The inference may be drawn either that the disease is not present in severe form or that the prompt measures taken in London to get serious cases into surroundings where they can be looked after have been successful. Liverpool reported 8 deaths from measles during the week, Willesden and Manchester each 5, Ilford, Leeds, and Preston each 3.

Deaths from influenza throughout the country remain nearly constant. This week they are scattered over 51 great towns, Middlesbrough reporting 5, Newcastle-upon-Tyne, South Shields, and Birmingham each 4, Ealing, Leeds, Sheffield, Leicester, and Nottingham each 3. Manchester reported 6 deaths from whooping-cough, Leeds 3, no other great town more than 2. Deaths from diphtheria were reported from 27 great towns, 3 each from Hull, Liverpool, and Newcastle-upon-Tyne.

The number of stillbirths notified during the week was 300 (corresponding to a rate of 44 per 1000 total births), including 44 in London. The number 300 has not been reached before since official notification was instituted.

IVORY CROSS FUND.—The annual general meeting of the Ivory Cross National Dental Aid Fund was held on March 12th. The council confirmed the decision of the executive committee, publicly announced over a year ago, not to accept donations which are the proceeds of gambling parties, nor in future to be associated with anyone employing such methods for raising money. The hope was expressed that their action would be widely followed by many charitable organisations which in the past had, under the pressure of need, accepted money that had been raised in this way. It was announced that the executive committee were negotiating with the commissioner for the special areas with a view to extending the work of the Ivory Cross Fund in certain special areas, with particular reference to the treatment of adolescents at junior instruction centres and at juvenile clubs. In present circumstances youths from 14 or 15 to 19 years of age are not entitled to dental benefit under the present health insurance Acts which, in any case, only give dental benefit to 50 per cent. of the male and 30 per cent. of the female members of approved societies.

MEDICAL NEWS

University of Oxford

On May 5th a proposal to establish an institute of experimental psychology at Oxford is to be put forward in convocation. An anonymous donor has already offered £10,000 towards the scheme, and Dr. William Brown will be proposed as first director.

University of Cambridge

On March 13th the following degrees were conferred:—
M.D.—R. Huxley Fish and M. S. Spink.
M.B. & B.Chir.—*J. R. Duffield, R. M. Yeo, and W. G. Q. Mills.
B.Chir.—C. U. Gregson and W. M. Beattie.
 * By proxy.

University of Edinburgh

The senatus of the University has resolved to offer the hon. degree of LL.D. to Dr. Mervyn Gordon, F.R.S., consulting bacteriologist to St. Bartholomew's Hospital, and Colonel the Hon. Murray Maclaren, M.D., lieutenant governor of New Brunswick.

The Paterson travelling scholarship has been awarded to Dr. G. Bowman Ludlam.

Congress of Experimental Cytology

The fourth International Congress for Experimental Cytology will be held in Copenhagen from August 10th to 15th. The chief subjects to be discussed are: the physical chemistry of the cell, histochemical problems and cell metabolism, experimental morphology, the electrophysiology of the cell, experimental cell pathology, and the biology of irradiation. Further information may be had from Dr. Harald Okkels, Institute for Pathological Anatomy, 11, Frederik 5' Vej, Copenhagen.

Royal College of Surgeons of England

A meeting of the council was held on March 12th with Sir Cuthbert Wallace, the president, in the chair. Mr. E. K. Martin was elected to the court of examiners, and Mr. F. N. Doubleday to the dental section of the board of examiners in dental surgery. It was decided that a graduate in dental surgery (M.D.S. or B.D.S.) of a recognised university in the United Kingdom shall in future be exempt from the whole of the first examination for the licence in dental surgery, and be admitted direct to the second and final examinations. It was also decided that private pupilage in dental mechanics need not necessarily be taken after the preliminary examination in general education has been passed.

A reception will be held at the College on Monday, July 6th.

It was decided that a further guarantee of £1625 from the Proffit trust fund should be given towards the expenditure of the governing body of the Radium Beam Therapy Research for 1937. Mr. G. E. Gask has undertaken to give a lecture on Feb. 15th, 1937, on the recently acquired Hunterian manuscripts relating to the British campaign in Portugal in 1762-3. Mr. Ernest W. Hey Groves was elected to represent the college on the General Medical Council, and on the inter-departmental committee of the Ministry of Health on the restoration of the working capacity of persons injured by accidents, and Sir Holburt Waring was elected representative of the college at the centenary celebrations of the University of London.

Licences in dental surgery were granted to the following:

Cecil Adair, G. H. Austin-Smith, N. A. Blay, O. B. Brears, W. H. Burndred, F. J. M. Bustard, A. O. Chick, G. R. Cogdon, R. F. Collens, D. C. J. Constable, W. F. Cooper, H. F. W. Dornhorst, T. P. Ellis, C. B. Frost, M. E. Gascoine, S. N. Ghose, W. H. Groom, G. A. B. Hoby, R. L. B. Hollick, Sidney Hurst, P. B. John, Tobias Kaufman, G. R. Lamont, J. L. MacDougall, J. D. Moore, M. R. Preston, H. C. Siggers, Erich Strasburger, E. F. J. Sumner, P. H. Tatchell, D. K. Toulson, K. J. Tovey, and R. S. Yates.

Diplomas in ophthalmic medicine and surgery were granted jointly with the Royal College of Physicians to the following:

Frank Badrock, P. N. Chaudhuri, J. E. Clark, T. K. Clifford, S. P. Divatia, G. B. Ebbage, W. H. V. D. Ferdinands, Frank Heckford, T. J. Howell, H. A. Ibrahim, F. J. Jensen, A. de B. Joyce, Joshua Mazell, B. F. Moore, Sidheshwar Nath, Triloki Nath, George Pollock, E. P. Tulloh, Norman Wren, and E. C. Zorab.

University of London

The following have been recognised as university teachers at the schools indicated: Dr. Una Ledingham (Royal Free Hospital), Dr. C. E. Brunton (London Hospital medical college), Mr. D. H. MacLeod (St. Mary's Hospital medical school), Mr. J. O. Irwin, D.Sc. (London School of Hygiene), and Dr. Duncan White (British Postgraduate medical school). Mr. J. D. Barris and Prof. F. J. Browne have been appointed examiners in obstetrics and gynaecology for the M.D. examination in 1936, and Dr. Doris Baker, Dr. Charles Porter, and Dr. Anna Broman as examiners for the diploma in the theory and practice of physical education in 1936.

A university chair of biochemistry tenable at St. Bartholomew's Hospital medical college and a university readership at the London Hospital medical college have been established. Applications should be sent to the registrar of the University at South Kensington, S.W.7, not later than March 31st for the chair, and April 15th for the readership.

The subject chosen for the Rogers prize essay for 1936 is the natural history of peptic ulcers. The competition is open to all registered practitioners of the United Kingdom, and the essays should reach the vice-chancellor by April 30th. Further information may be had from the academic registrar.

National University of Ireland

On March 12th the degree of M.D. was conferred on M. P. O'Connor. Dr. Timothy Donovan was appointed to the lectureship in materia medica, and Dr. E. V. Cantillon to the lectureship in therapeutics, in University College, Cork.

Auxiliary Royal Army Medical Corps Funds

The annual meeting of members will be held at 5.15 p.m. on Friday, April 3rd, at 11, Chandos-street, when the financial statement for 1935 will be presented and the officers and committee for the current year elected.

Congress on Physical Medicine

The sixth International Congress of Physical Medicine will be held in London from May 12th to 16th under the presidency of Lord Horder. The hon. secretary is Dr. Albert Eidinow, 4, Upper Wimpole-street, W. 1. Lord Horder will take the chair at a luncheon at the Langham Hotel on April 8th, when he is to give an address on the progress of physical medicine with special reference to the congress.

Institute of Medical Psychology

The research fellowship offered by the Rockefeller Foundation and tenable at this institute has been awarded to Dr. A. T. Wilson for research into the relation between the emotional and organic factors in certain physical disorders. Dr. Wilson, a graduate of Glasgow and an assistant physician at the institute, was formerly senior assistant in the department of physiology at the Middlesex Hospital.

British Postgraduate Medical School

An intensive course intended primarily for practitioners will be held at this school from April 15th to 26th (10.30 to 4.30 daily). Among those giving lectures and demonstrations will be Prof. F. R. Fraser, Dr. John Parkinson, Prof. James Young, Dr. Chassar Moir, Mr. B. W. Williams, Dr. R. D. Lawrence, Mr. A. J. Watson, Dr. R. T. Brain, Sir David Wilkie, Dr. H. Crichton-Miller, Dr. Janet Vaughan, Mr. P. H. Mitchiner, Mr. F. M. Loughnane, and Dr. G. W. Bray. Sessions will also be held at the Royal London Ophthalmic Hospital; the Hospital for Sick Children, Great Ormond-street; the National Hospital, Queen-square; and the Central London Throat, Nose, and Ear Hospital. Early application for membership of this course is recommended, and further information may be had from the dean of the school, Ducane-road, London, W.12.

On Thursdays from April 9th to May 14th at 2.30 p.m. Dr. W. S. C. Copeman will give six lectures on arthritis.

The King has given permission to Dr. S. M. Vassallo to wear the insignia of the third class of the order of the Brilliant Star of Zanzibar which has been conferred on him by the Sultan.

Aberdeen University Club, London

The ninety-fifth half-yearly dinner will be held at the Café Royal at 7.30 p.m. on Thursday, April 2nd. The chairman of the evening will be Lord Alness, and the hon. secretary's address is 51, Harley-street, London, W.1.

Medical Meeting at Manchester

In connexion with a two-day regional conference of the British Social Hygiene Council a special meeting, for medical men and women only, will be held in the chemistry theatre of the University of Manchester, on Friday, March 27th, at 8 p.m., when Dr. Morna Rawlins, of Guy's Hospital, will speak on the treatment of gonorrhœa in women, and Dr. Tytler Burke, of Salford, on the child with congenital syphilis. Dr. J. J. Butterworth, county medical officer of Lancashire, will be in the chair.

A Badge for Medical Motorists

As reported in our Parliamentary Intelligence, the Minister of Transport was recently asked if he would authorise the attachment of a special badge or the use of a distinctive horn on the cars of medical practitioners, in order that the police might allow them facilities in emergency. Assured that the plan had worked well in Canada, Mr. Hore-Belisha said he would look into the question. We are now informed that the National Motorists' Association is issuing to 40,000 medical men a badge incorporating the red cross, which, it is hoped, will help the public to identify their cars, and give their owners priority or preferential treatment.

British Red Cross Units in Abyssinia

Mr. J. M. Melly, in charge of the first British Red Cross Ambulance Unit, which is now in the neighbourhood of Lake Ashangi, and is treating about a hundred wounded lake, reports heavy losses of stores and material as the result of air bombing. Ten tents have been totally destroyed and 25 are perforated and unusable. All but two weeks' supply of medical and surgical stores are destroyed. Native personnel from the Kenya and Somaliland border, who after the bombardment asked to be repatriated, have left for Dessie in charge of an officer returning to their own country.

Subscriptions towards the work of the two units now in Abyssinia may be sent to the British Red Cross Society, 14, Grosvenor-crescent, London, S.W.1. The cost of maintaining them in the field, apart from unexpected losses, is estimated at £3000 a month.

Tuberculosis Association

The provincial meeting of this society will be held at the Physiology School, Cambridge, on April 2nd, 3rd, and 4th under the presidency of Dr. L. S. T. Burrell. The conference will be opened by a discussion on dispensary organisation at which Dr. R. H. Hazemann (médecin inspecteur of the Seine prefecture), Dr. Heynsius van den Berg (director of the Amsterdam tuberculosis service), and Dr. N. Tattersall (tuberculosis officer, Leeds) will speak. Dr. Russell Reynolds will also give a demonstration of cinematography of the chest. On Friday morning there will be a joint meeting of the association with the international after-care committee of the Union Internationale contre la Tuberculose which will be opened by Prof. Ferd. Bezançon (secretary-general of the union). Dr. Maurice Davidson and Dr. L. B. Stott will read a paper on the capacity for work in pulmonary tuberculosis, and Prof. von Weizsäcker (director of the Heidelberg medical clinic) and Dr. E. Bachmann (secretary of the after-care committee) will also speak. A visit will be paid in the afternoon to Papworth, where there will be a discussion on schemes for after-care to which Dr. Bronkhurst (Berg en Bosch, Bilthoven) and Dr. Pattison (Potts Memorial Hospital, New York) will contribute. On Saturday Prof. Sayé (Barcelona) will speak on chronic miliary tuberculosis, and cases for discussion will be presented by Dr. S. Vere Pearson, Dr. G. T. Hebert, and Mr. H. P. Nelson. The hon. secretary of the association is Dr. Frederick Heaf, Colindale Hospital, London, N.W.9.

Demonstrations of Contraceptive Technique

On Thursday, April 2nd, at 2.30 p.m., at the clinic of the Society, a demonstration of the technique of the use of a variety of contraceptive methods will be given by Mrs. Marie Stopes, D.Sc., and Dr. Evelyn Fisher. Applications for tickets from medical practitioners and senior students should be sent to the hon. secretary, C.B.C., 108, Whitfield-street, London, W.1.

Naval Medical Compassionate Fund

A meeting of the subscribers of this fund will be held at 3.15 p.m. on Friday, April 24th, at the Medical Department, Admiralty, London, S.W.1, to elect six directors.

Fellowship of Medicine and Post-Graduate Medical Association

All-day courses have been arranged in infants' diseases (March 30th to April 4th); in proctology, at St. Mark's Hospital (April 20th to 25th); and in medicine, surgery, and gynaecology, at the Royal Waterloo Hospital (April 27th to May 9th). Afternoon courses will also be held in psychological medicine, at the Maudsley Hospital (April 27th to May 30th), and in ophthalmology, at the Royal Eye Hospital (April 20th to May 1st); and week-end courses at the Victoria Park Hospital in diseases of the heart and lungs (April 18th and 19th), and at the National Temperance Hospital in medicine and surgery (April 4th and 5th). Courses are open only to members and associates of the Fellowship, and further information may be had from the secretary of the Fellowship, 1, Wimpole-street, London, W.1.

University Travel Guild

The University Travel Guild inaugurated a series of Travel Lunches at the Criterion Restaurant on Tuesday last. It is the first organisation of the kind to arrange an air tour for its members, so it was appropriate that the speakers, Mr. Lindsay Everard, M.P., and Miss Amy Johnson, should be famous figures in the flying world. The room was crowded and the audience were much interested in Mr. Everard's address and no doubt noted his remarks on the low cost of the Easter tour to Central Europe which was being organised by the Guild. The flying, he said, worked out at 3½d. a mile, while hotel accommodation, all meals, and sightseeing only added 1½d. a mile to the expense.

The next lunch is being held on May 5th, when H.E. The Yugoslav Minister will be the speaker. All particulars can be obtained from the secretary of the Guild, 25, Cockspur-street, S.W.1.

Dinner to Dr. and Mrs. Fairbairn

On March 5th a dinner was held in the Langham Hotel to bid farewell to Dr. and Mrs. J. S. Fairbairn on the occasion of their leaving London to reside in Lossiemouth. Over one hundred guests were present. Sir Ewen Maclean, president of the British College of Obstetricians and Gynaecologists, was in the chair, and in a happy speech pointed out how much Dr. Fairbairn had furthered the teaching and practice of midwifery throughout Britain. He expressed the general regret at the retirement of Dr. Fairbairn from active practice, and assured him of a warm welcome whenever he came back to London. Dr. Herbert Spencer referred to the impulse which had attracted Dr. Fairbairn to London. Miss Pye, president of the Midwives' Institute, spoke of the support which the interests of the midwives had always received from him, and Lady Richmond, on behalf of the Central Midwives Board, endorsed this acknowledgment. Sir William Willcox, master of the Society of Apothecaries, spoke in warm terms of the affection in which Dr. Fairbairn and Mrs. Fairbairn were held. Dr. Fairbairn, who was greeted with song and cheers, expressed the pleasure it gave him to be received so kindly by so many of his colleagues on the various bodies on which he had served. He preferred to say goodbye and go when the going was good. He would always carry with him the memory of this welcome and farewell. A silver rose bowl with an album of signatures was presented to Dr. and Mrs. Fairbairn by the chairman on behalf of the guests present, and many colleagues from far and near who wrote regretting their inability to attend.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Health Conditions in Offices

IN the House of Commons on March 13th Mr. CREECH JONES moved the second reading of the Offices Regulation Bill. He said that there was practically no systematic or routine inspection of offices to-day, and in view of the appalling conditions which existed in many offices it was evident that the existing legislation was inadequate. All the organisations concerned with clerical workers were pressing for this Bill. There was to-day increasing nervous strain on the workers. It was important that they should have a standard of conditions which would ensure their health. Doctors had said that there was a tendency among clerical workers towards tuberculosis and digestive and nervous disorders arising in part from the conditions of employment. The Bill was based on the report of the Select Committee on Shop Assistants in 1931 and was in accordance with its recommendations and with the methods adopted by the Home Office in recent legislation. The first part of the measure dealt with the sanitation and general conditions in offices, and the second part with the employment of young persons in offices.

Mr. LATHAN, in seconding, said that the Bill provided the Government with an opportunity to show that they were desirous of doing something to protect the health and interests of the non-manual workers. The existing factory and shops legislation would not meet the needs of the situation.

Mr. LEVY moved :

"This House declines to give a second reading to a Bill which, so far as it is efficiently workable, merely re-enacts the existing law in different words, and which will lead to confusion in administration because it brings under its provisions offices which in many cases are regulated either by the Factory Acts or the Shops Acts."

He said that the passing of the Bill would lead to confusion in administration, because it brought under its provisions offices which in many cases were regulated either by the Factory Acts or the Shops Acts.

After further debate,

Sir FRANCIS FREMANTLE said he could reinforce what had been said about the difficulty of complaints. Medical officers of health knew that the law relied upon complaints being brought forward, and it was ridiculous to think that the ordinary employee in an office would bring forward complaints. Vital statisticians themselves had shown that those who entered offices were often those who were less robust; in fact a considerable proportion of those who entered offices were in one way or other delicate. If they were not definitely affected with tubercle they were susceptible to it. Certainly the conditions of working in offices were very inferior from the health point of view compared with those affecting agriculture. Therefore there was all the more reason for improving office conditions. There had been an immense advance in public health in recent years because of the system under which sanitary inspectors and medical officers of health worked, and latterly because of the appointment of health visitors. Much could be done by settling matters through persuasion. There was however the old-time conflict between the Ministry of Health and the Home Office. The medical officers of health for the metropolis did not think that they had the power of inspection. It would be greatly to the advantage of the administration if the law definitely said that work place did include offices and that there was power of inspection without the medical officers having to wait for suspicion of a nuisance.

THE UNDER-SECRETARY'S REPLY

Mr. GEOFFREY LLOYD agreed with what had been said about the increasing importance of office workers. Between 1921 and 1931 the total number of the employed population increased by 10 per cent., but the number of clerical workers increased by 38 per cent. Figures had been given of the tuberculosis-rate among office workers, but there were other classes of indoor workers who unfortunately had a higher tuberculosis mortality. It was argued that the tuberculosis-rate among office workers was due to their working conditions, but certain classes of workers who had higher mortality-rates were subject to the stringent conditions of the Factory Acts in their work. The Government were taking steps to improve the health of office workers and others. There were proposals for the increased organisation of physical education and recreation. Also the provision whereby clerical workers who were not at present governed by a pension scheme could come in on a voluntary basis was valuable. Nobody was quite certain how far the Public Health Acts would be a solution of the problem, or what the position regarding them was. Those Acts dealt with the most important of the provisions concerning sanitation, ventilation, overcrowding, and so on, which were dealt with in the Bill now before the House. But he would not say that the present position under the Public Health Acts was completely satisfactory. Doubts had been continuously raised whether the definition "workshop" included an office and about the general powers of inspection irrespective of complaints. The draft Bill for the Consolidation of the Public Acts—which would be introduced almost immediately—would effect very important changes in matters as they stood at present. It would give powers for the inspectors of local authorities to enter offices. That would produce a body of opinion and knowledge for dealing with special abuses. As the consolidating Bill was being introduced by the Government and would meet the most important needs of the situation he asked that the present Bill should not be given a second reading.

The motion for the second reading of the Bill was negatived by 134 votes to 93. The amendment was then agreed to 109 votes to 78.

Disposition of the Dead

At a meeting of the National Health and Housing Committee on March 11th, Sir FRANCIS FREMANTLE in the chair, Mr. Murray Phelps spoke on the work of the National Council for the Disposition of the Dead. The Council, he said, was concerned to secure revision and codification of the laws in relation to burial and cremation. Under the leadership of Lord Horder, and with the support of affiliated bodies, they were emphasising the public health importance of this question, it being increasingly recognised that the sanitary disposition of the dead and the health of the living are closely related. With the continuous growth of great towns, the sterilisation of land for the erection of cemeteries was regrettable and uneconomic, especially now when crematoria were becoming easily accessible in most parts of the country. Since 1926 the number of cremations had increased from 2800 to over 9000 per annum, and it was hoped to reach the 10,000 mark this year. Mr. Phelps closed by asking the committee to give sympathetic consideration to a Bill for the registration of undertakers that would be introduced in the near future. Mr. R. B. V. Perkins, of the Cremation Society, followed with a brief account of the insurance scheme which now enables the working classes to provide for cremation on the lines which have proved so successful on the continent.

Mr. E. H. Keeling, M.P., has been elected to assist Captain G. S. Elliston in the secretarial work of the Health and Housing Committee.

National Physique and Fitness of Recruits

In the House of Lords on March 17th a debate took place on a motion by Viscount SWINTON, Secretary of State for Air, approving the Government's defence proposals as outlined in the White Paper.

The Earl of CAVAN said that the only disquieting thing in the White Paper was the shortage of picked men. Roughly, 50 per cent. of the applicants were rejected. That was a national reproach. It could be remedied, not by lowering the recruiting standard, but by paying much more attention to the physical condition of the young men of the nation. What was wanted were more food and more open-air games. If measures were now taken seriously to improve the physical welfare of the youth of this country, our recruiting problems would soon be solved.

The debate was adjourned.

In the House of Lords on March 17th, on the motion of Earl DE LA WARR, Parliamentary Secretary to the Board of Education, the Milk (Extension of Temporary Provisions) Bill was read the third time, and passed.

On March 17th, in the House of Lords, Lord BALFOUR of BURLEIGH introduced the Public Health London Bill and Viscount GAGE introduced a Bill to consolidate the enactments relating to National Health Insurance.

Both Bills were read a first time.

HOUSE OF COMMONS

WEDNESDAY, MARCH 11TH

Motor Facilities for Medical Practitioners

Mr. DAY asked the Minister of Transport whether, in view of the many urgent calls made on registered medical practitioners, he would authorise the attachment on their cars of a special badge, and/or consider allowing them the use of a distinctive horn, in order that the police might allow them special facilities to proceed on their way in the case of emergency.—Mr. HORE-BELISHA replied: This suggestion has always been considered impracticable in view of the impossibility of preventing abuse.

Mr. DAY: Is the Minister aware that this plan has worked very satisfactorily in Canada?—Mr. HORE-BELISHA: I was not aware of that fact. If the hon. Member will submit the facts to me I will be glad to look into them.

Guide Dogs for Blind ex-Service Men

Colonel SANDEMAN ALLEN asked the Minister of Pensions whether he was aware that a centre existed at New Brighton for the training of guide dogs for the blind; and whether he was prepared to assist in the provision of these dogs for blind ex-Service men.—Sir JAMES BLINDELL (Lord of the Treasury) replied: The answer to the first part of the question is in the affirmative. I am informed that the Ministry have no fund out of which such assistance could be given. It may be pointed out, however, that a special weekly allowance, in addition to pension, is provided by the Ministry for all cases of total blindness needing constant attendance. Having regard to present-day conditions of road traffic, this is considered to be the more suitable form in which assistance in such cases should be given.

THURSDAY, MARCH 12TH

Medical Attention in Juvenile Training Centres

Brig.-General SPEARS asked the Minister of Labour whether the recommendation of the commissioner for the special areas that simple medical treatment should be given to boys and young men who were prevented from benefiting by training schemes on medical grounds was being complied with; and, if not, if he would assure the House that a decision in regard to this matter would be announced shortly.—Lieut.-Colonel MUIRHEAD (Parliamentary Secretary to the Minister of Labour) replied: Education authorities in England and Wales have power to provide medical treatment for juveniles attending the junior instruction centres conducted by them, and it is my right hon. friend's policy to encourage authorities to make this provision. As regards young men my right

hon. friend is considering with the Departments concerned the medical services already available and the extent, if any, to which it may be necessary to supplement them in the special areas to fit young men for training. I hope that it will be possible to reach a decision shortly.

Vermin-infested Bricks

Mr. KIRBY asked the Minister of Health whether he was prepared to introduce legislation whereby vermin-infested old bricks taken from demolished dwelling-houses should be prohibited from use in the construction of new dwelling-houses of any kind.—Sir KINGSLEY WOOD replied: In view of the power conferred on local authorities by Section 82 of the Housing Act, 1935, to cleanse from vermin any house to which a demolition order or clearance order applies before it is demolished, I do not consider further legislation necessary.

Sulphuric Acid and the Poisons Act

Mr. WILLIAM DUCKWORTH asked the Home Secretary whether he would take steps to amend the Pharmacy and Poisons Act, 1933, so as to make it clear that it was not obligatory for garages and wireless dealers who engaged in the charging of accumulators to be registered as sellers of poisons in so far as such charging involved the use of sulphuric acid.—Sir JOHN SIMON replied: No, Sir. The sale of sulphuric acid in accumulators is clearly exempted from the provisions of the Act by Rule 11 and the third Schedule of the Poisons Rules, 1935.

MONDAY, MARCH 16TH

Bombing of British Red Cross by Italian Aircraft

Mr. WEDGWOOD asked the Secretary of State for Foreign Affairs what had now been done concerning the bombing of the British ambulance by Italian airmen.—Viscount CRANBORNE (Under-Secretary for Foreign Affairs) replied: Since the statement which I made on this subject on Monday last, the Italian Government have communicated a written reply to the representations made by H.M. Ambassador in Rome, a telegraphic summary of which has been communicated by Sir Eric Drummond to my right hon. friend. So far as can be judged from this summary, the Italian Government admit the bombing on March 4th of an encampment furnished with at least one Red Cross sign, but claim that this bombing was in retaliation for the opening of fire upon the aircraft both on March 3rd and 4th. It is claimed that the Italian aircraft were fired on yet again on March 5th from the same locality, but the summary does not show that the Italians admit having bombed the encampment again on that day. The Italian note apparently states that the coincidence of the locality and of the facts permits the identification of this alleged incident with that of which H.M. Government had complained. As to this I can only say that my right hon. friend has noticed considerable discrepancies between the account given in the Italian communication and the report previously communicated by the leader of the British Red Cross Unit concerned, particularly as regards the number of lorries and of Red Cross insignia as well as the location of the encampment. The Italian official statement does not apparently specify who is supposed to have fired on the aircraft, but the Italian press of March 12th explain that it was done by at least a thousand armed men in khaki uniform who emerged from the tents on the approach of the aircraft. Dr. Melly has already denied that there was any firing upon Italian aircraft from the neighbourhood of his camp, but further detailed information is being sought from him. The right hon. gentleman may be assured that H.M. Government will pursue this matter with the utmost energy with the Italian Government as soon as my right hon. friend has obtained Dr. Melly's further comments.

Coal Fires and Atmospheric Pollution

Mr. DAVID ADAMS asked the First Commissioner of Works if he was aware that the department of industrial and scientific research and the leading municipalities of the United Kingdom agreed that coal-burning fires were the prime cause of atmospheric pollution causing injury to the public health and public buildings, added risks to aviation, and other disabilities; why almost all the offices and departments under his control in London were heated

with raw coal; and whether he would introduce and gradually extend the use of smokeless fuel as in the lobbies of this House.—Mr. ORMSBY-GORE replied: Yes, Sir. I am aware of the causes and effects of atmospheric pollution, but I understand that there is a ready market for all the present production of smokeless fuel suitable for open fireplaces; the total sale would not be increased by any order I might give and the question of atmospheric pollution would not be affected. About two-thirds of the accommodation under my control in London is heated by plants consuming smokeless fuel of various kinds; for open fireplaces suitable smokeless fuel is used wherever local circumstances make it possible without unreasonable increase of cost. Apart from the fact that there was some dissatisfaction when smokeless fuel was used in the lobby fires some time ago, I should not be justified at present prices in using smokeless fuel in the fireplaces of this House.

Blind and Insane Pensioners

Mr. MCGOVERN asked the Minister of Pensions the total number of blind and insane persons on pension in Great Britain from the result of the war 1914–18.—Sir JAMES BLENDLELL (Lord of the Treasury) replied: I am informed that the number of pensions in payment in respect of eye affections assessed at 100 per cent. is approximately 1990. The number of pensioners certified as of unsound mind in mental institutions is about 5990.

Sir John Orr's Report on Malnutrition

Mr. ELLIS SMITH asked the Prime Minister if he would consider the Report prepared by Sir John Boyd Orr, and take steps to set up a ministry for food-supply and organise a national distribution of food.—Mr. BALDWIN replied: The report is being referred by my right hon. friend the Minister of Health to the Advisory Committee on Nutrition for examination. The answer to the last part of the question is in the negative.

Mr. JOHNSTON asked the Minister of Health whether he was aware of the serious reports by Sir John Boyd Orr and the staffs of the Rowett Institute and the Market Supply Committee as to the under-nourishment of 10 per cent. of the population and the under-nourishment combined with defective nutrition of other 40 per cent. of the population; whether he was aware of the increasing public health expenditure required as ambulance work owing to this defective nutrition; and what steps the Government proposed to take to cope with the situation.—Sir KINGSLEY WOOD replied: I am aware of these reports and I am referring them to my Advisory Committee on Nutrition for examination.

General Nursing Council Rules

Mr. OSWALD LEWIS asked the Minister of Health if he would give the British Hospitals' Association an opportunity of expressing their opinion upon the new regulations drafted by the General Nursing Council for England and Wales, regarding a proposed educational standard for nurses before he gave his formal approval of such regulations.—Mr. SHAKESPEARE (Parliamentary Secretary to the Ministry of Health) replied: Yes, Sir. My right hon. friend has already done so and he is in communication with the Association on the matter.

Infectious Disease in County Durham

Mr. DAVID ADAMS asked the Minister of Health whether he was aware of the high incidence of infectious disease in the Stanley, County Durham, area, and that this was declared by members of the local authority to be due to the low nutritional standards of the area; and whether he would investigate this situation.—Mr. SHAKESPEARE replied: My right hon. friend is aware of this outbreak; the situation has been under close investigation for some time past, and he is now awaiting a report by the county medical officer of health.

Pasteurisation

Mr. DE ROTHSCHILD asked the Minister of Health whether, in view of the health value of pure clean raw milk, and in view of the high standard of cleanliness of tuberculin-tested milk, he would reconsider the proposal to institute a separate grade of tuberculin-tested pasteurised milk, in order not to restrict the market for the highest grades of pure raw milk by fostering the idea that the safety of even tuberculin-tested milk would be

enhanced by pasteurisation.—Mr. SHAKESPEARE replied: My right hon. friend is giving consideration to this matter in the preparation of the new Special Designations Order.

Milk for Nursing Mothers and Infants

Mr. JOHNSTON asked the Minister of Health whether his attention had been called to the report of the Medical Research Council for 1934 to 1935, just issued, urging the importance of the consumption of more liquid milk by pre-school children and nursing mothers; and whether he would consult with the Secretary of State for Scotland and the Minister of Agriculture with a view to immediate steps being taken to give effect to this recommendation.—Mr. SHAKESPEARE replied: Yes, Sir. My right hon. friend intends to give full consideration to this report in consultation with my right hon. friends the Secretary of State for Scotland and the Minister of Agriculture.

TUESDAY, MARCH 17TH

Typhoid Fever in Derbyshire

Mr. HOLLAND asked the Minister of Health if he was aware that the outbreak of typhoid fever in the village of Langwith, Derbyshire, was reported to be due to a previous water-supply which was pronounced by the district medical officer to be polluted; that at a recent date one person died from the alleged effects of typhoid fever; and in what way compensation would be made, as there was much local indignation concerning this matter.—Sir KINGSLEY WOOD replied: The answer to the first two parts of the question is in the affirmative. As regards the last part, the question of liability to pay compensation is not one on which I can express any opinion. It is a matter which can be determined only by the courts.

Influenza at Chatham Barracks

Captain PLUGGE asked the Secretary of State for War the number of cases of influenza or similar complaints which had occurred within the last month in the Brompton Barracks, Chatham; what had been the death roll; and why in the case of normal colds the mortality had been relatively high.—Mr. DUFF COOPER replied: During the last month there have been 25 cases of influenza, 5 of pneumonia, 3 of bronchitis, and 198 of common cold at Brompton Barracks, Chatham. Four deaths have occurred, three being the result of broncho-pneumonia, influenzal in origin, and the other of lobar pneumonia. Every possible precaution has been taken to prevent the spreading of the outbreak, and reports show that, since the beginning of this month, there has been a steady reduction in the number of admissions to hospital and of barrack treatment.

Births, Marriages, and Deaths

BIRTHS

KIES.—On March 9th, at Hitchin, the wife of Dr. Jean Kies, of Letchworth, of a daughter.
ROBERTS.—On March 15th, the wife of O. W. Roberts, M.D. Lond., F.R.C.S. Eng., Medical Superintendent, Dulwich Hospital, S.E., of a daughter.
WHITCHURCH HOWELL.—On March 11th, 1936, to Frances, née Roper Blackwood, wife of Bernard Whitchurch Howell, F.R.C.S., of 123, Harley-street, W.1—a daughter.

MARRIAGES

FRANCE—POTTER.—On March 8th, at the Parish Church, Ashted, Herbert France, M.R.C.S. Eng., to Muriel Beatrice Potter.

DEATHS

ANDREWS.—On March 13th, at St. Briavel's House, Gloucestershire, Surg. Capt. O. W. Andrews, C.B.E., M.B. Durh., R.N.
CASH.—On March 14th, at Bovey Tracey, S. Devon, Alfred Midgley Cash, M.D. Edin., aged 85.
CAWTHORNE.—On March 12th, Benjamin Walker Cawthorne, M.D. Edin., late of Bath, aged 78.
GRIFFIN.—On March 10th, Ernest Harrison Griffin, D.S.O., M.C., M.R.C.S. Eng.
HALDANE.—At midnight, March 14th–15th, at Chervell Oxford, Prof. John Scott Haldane, C.H., F.R.S., M.D., LL.D. Edin., Fellow of New College, Oxford, aged 75.
MCGEAGH.—On March 12th, at Ramsey, Isle of Man, Robert Thomas McGeagh, M.D. R.U.I., in his 78th year.
WASON.—On March 16th, at Lichfield, Clevedon, Richard Llewellyn, M.R.C.S., L.R.C.P. Lond., eldest son of the late J. E. F. and Annie Wason, and beloved husband of Mary Kathleen Wason.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

- ROYAL SOCIETY OF MEDICINE**, 1, Wimpole-street, W.
MONDAY, March 23rd.
Odontology, 8 P.M. Mr. F. N. Doubleday: 1. Third Molar Removed from Behind the Orbit. 2. Third Molar Removed from Beneath the Tongue. 3. A Case of Facial Deformity Referred by an Industrial Firm. Mr. W. E. Herbert: 4. Unruptured Supernumerary Tooth Causing Death of the Pulp of a Central Incisor. 5. Congenital Absence of Teeth. 6. Fracture of the Roots of Two Incisors where the Pulp has Remained Vital. Mr. G. T. Hankey: 7. Bilateral Perforation of the Antrum and Nose following Chronic Necrosis of the Maxilla. 8. Complete Caries of Permanent Dentition—except Wisdoms—at the age of 13, in an otherwise Normal Boy.
TUESDAY.
Medicine, 5 P.M. Sir Walter Langdon-Brown, Dr. A. P. Thomson, and Dr. P. M. F. Bishop: Medical Aspects of the Menopause.
WEDNESDAY.
Comparative Medicine, 4 P.M. (Royal Veterinary College, Great College-street, N.W.) Demonstrations in Research Institute and College.
THURSDAY.
Urology, 8.30 P.M. Mr. John Everidge: 1. "Staghorn" Calculus Removed from a Single Kidney. Mr. A. E. Roche: 2. Nephrectomy for Uterovaginal Fistula. Mr. Reginald T. Payne: 3. Hyperparathyroidism, including Renal Calculi. Mr. Morton Whitby: 4. Enlarged Prostate (Enucleation-suprapubic with Complete Closure of Bladder). 5. Left Pelvic Renal Calculi with Hydronephrosis Complicated by Acute Gonorrhoea. Mr. H. P. Winsbury-White: 6. Two Cases of Retention of Urine in Women. Mr. James Carver: 7. Blind Supernumerary Ureter. 8. Tuberculous Ureteric Stump. 9. Stricture of the Ureter with Hydro-ureter and Hydronephrosis. Mr. Edgar Freshman: 10. Infected Hydronephrosis in a Horse-shoe Kidney.
FRIDAY.
Physical Medicine, 5.30 P.M. (St. John Clinic and Institute of Physical Medicine, Ranelagh-road, S.W.) Demonstrations and Clinical Cases by Sir Leonard Hill, Mr. Timbrell Fisher, Dr. Francis Bach, Dr. A. P. Cawadias, Dr. Philip Ellman, Dr. Charles Robinson, Dr. Gordon Calthrop, and Dr. Albert Eidinow.
Disease in Children: Obstetrics and Gynaecology: Epidemiology and State Medicine, 4.45 P.M. Dr. J. B. Blaikley and Dr. G. F. Gibberd: Mechanism of Atelectasis and its Treatment by Intratracheal Insufflation. Dr. N. B. Capon, Prof. G. I. Strachan, Dr. Letitia Fairfield, and Dr. Ethel Cassie: The Prevention of Neonatal Death, Injury, and Disease.
MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.
MONDAY, March 23rd.—8.30 P.M., Prof. G. Grey Turner: Surgery of the Oesophagus.
MEDICO-LEGAL SOCIETY.
THURSDAY, March 26th.—8.30 P.M. (Manson House, 26, Portland-place, W.), Dr. L. A. Weatherly: Debatable Medico-legal Episodes in the Long Life of an Alienist.
ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY, 5, Lisle-street, W.C.
WEDNESDAY, March 25th.—4.30 P.M., Clinical Meeting.
BRITISH PSYCHOLOGICAL SOCIETY.
WEDNESDAY, March 25th.—8.30 P.M. (11, Chandos-street, W.), Dr. H. Godwin Baynes: The Importance of Dream Analysis for Psychological Development. Dr. J. A. Hadfield and Dr. C. Wilson will also speak. (Medical Section.)
SOCIETY OF MEDICAL OFFICERS OF HEALTH.
FRIDAY, March 27th.—3.45 P.M. (Park Hospital, Hither Green, S.E.), Dr. H. S. Banks: Clinical Demonstration. (Fever Hospitals Medical Service Group.)
ASSOCIATION OF INDUSTRIAL MEDICAL OFFICERS.
FRIDAY, March 27th.—5.45 P.M. (London School of Hygiene and Tropical Medicine, Keppel-street, W.C.), Air Vice-Marshal Sir David Munro and Dr. T. M. Ling: Physical Standards in Industry. Dr. Ling: Psychological Factors in Sickness Absenteeism.
SATURDAY.—10 A.M., Dr. R. E. Lane: The Prevention of Industrial Plumbism.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

- ROYAL COLLEGE OF PHYSICIANS**, Pall Mall East, S.W.1
TUESDAY, March 24th, and **THURSDAY**.—5 P.M., Mr. Joseph Needham, Sc.D.: Chemical Aspects of Morphogenetic Determination. (Oliver-Sharpey Lectures.)
ROYAL COLLEGE OF SURGEONS, Lincoln's Inn-fields, W.C.
MONDAY, March 23rd.—5 P.M., Dr. L. W. Proger: New Additions to the Museum.
UNIVERSITY OF BIRMINGHAM.
FRIDAY, March 27th.—3.30 P.M. (Queen's Hospital), Prof. Philip Cloake: Diabetes Mellitus.

- ROYAL INSTITUTION**, 21, Albemarle-street, W.
TUESDAY, March 24th.—5.15 P.M., Prof. Edward Mellanby, F.R.S.: Drug-like Actions of Some Foods.
INSTITUTE OF HYGIENE, 28, Portland-place, W.
WEDNESDAY, March 25th.—3.30 P.M., Dr. J. F. Halls: Dally: Psychological Influences on the Circulation.
BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducaane-road, W.
MONDAY, March 23rd.—2.30 P.M., Dr. Gordon Holmes, F.R.S.: Cerebro-spinal Syphilis.
TUESDAY.—2.30 P.M., Dr. Miles: Normal and Abnormal Bacterial Flora.
WEDNESDAY.—Noon, Clinical and pathological conference (medical). 2.30 P.M. Clinical and pathological conference (surgical). 3.30 P.M., Mr. Aleck Bourne: Disproportion and Difficult Labour.
THURSDAY.—2.15 P.M., Dr. Duncan White: Radiological demonstration. 3 P.M., Dr. Chassar Moir: Operative Obstetrics.
FRIDAY.—Noon, Dr. A. A. Davies: Gynaecological Pathology. 3.30 P.M., Dr. Alan Moncrieff: Hygiene of the New-born Child. 5 P.M., Sir James Walton: Surgical Aspects of Dyspepsia.
 Daily, 10 A.M. to 4 P.M., Medical Clinics, Surgical Clinics or operations, Obstetric and Gynaecological Clinics or operations.
FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, March 23rd, to **SUNDAY**, March 29th.—**INFANTS HOSPITAL**, Vincent-square, S.W. Mon., Wed., and Fri. at 8 P.M., primary F.R.C.S. course in anatomy and physiology.—**ROYAL CHEST HOSPITAL**, City-road, E.C. Mon., Wed., and Fri., 8 P.M., special M.R.C.P. class in chest and heart diseases.—**NATIONAL TEMPERANCE HOSPITAL**, Hampstead-road, N.W. Wed., 8.30 P.M., Dr. Reginald Lightwood: Modern Views Concerning Tuberculosis in Children.—**ALL SAINTS' HOSPITAL**, Austral-street, S.E. Sat. and Sun., course in urology. Courses are open only to members of the fellowship.
KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.
TUESDAY, March 24th.—4.30 P.M., Mr. H. A. T. Fairbank: Some General Affections of the Skeleton.
HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W.
THURSDAY, March 26th.—3 P.M., Dr. Russell Brain: Demonstration.
NATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, March 23rd.—3.30 P.M., Dr. Symonds: Head Injuries (III.).
TUESDAY.—3.30 P.M., Dr. Grainger Stewart: Meningitis and Cerebral Abscess.
WEDNESDAY.—3.30 P.M., Dr. Kinnier Wilson: Clinical Demonstration.
THURSDAY.—3.30 P.M., Dr. Riddoch: Cerebral Tumours.
FRIDAY.—3.30 P.M., Dr. Denny-Brown: Neuritis. Out-patient clinic daily at 2 P.M.
HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
WEDNESDAY, March 25th.—2 P.M., Dr. Wilfred J. Pearson: Deformities of the Chest—Effect upon Respiration. 3 P.M., Dr. W. W. Payne: Sedimentation-rate in Tuberculosis. Out patient Clinics daily at 10 A.M. and ward visits at 2 P.M.
NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W.
TUESDAY, March 24th.—5.30 P.M., Dr. F. W. Price: Angina Pectoris.
HAMPSTEAD GENERAL HOSPITAL, N.W.
WEDNESDAY, March 25th.—4 P.M., Dr. H. Van Praagh: Some Pitfalls of General Practice.
MANCHESTER ROYAL INFIRMARY.
FRIDAY, March 27th.—4.15 P.M., Mr. W. R. Douglas: Demonstration of Surgical Cases.
ANCOATS HOSPITAL, Manchester.
THURSDAY, March 26th.—4.15 P.M., Mr. E. E. Hughes: Acute Surgical Conditions of the Kidney.
LEEDS GENERAL INFIRMARY.
TUESDAY, March 24th.—3.30 P.M., Dr. J. T. Ingram: Some Dermatological Neuroses.
GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.
WEDNESDAY, March 25th.—4.15 P.M. (Victoria Infirmary), Mr. Robert Tennent: The Gall-bladder.

ST. ANDREW'S HOSPITAL, DOLLIS HILL.—Plans are being prepared for an extension to the nurses' home of this hospital, and building will probably begin in the spring. The cost will be about £6000, and there is already a debt on the first part of the home and new buildings of £3623. The hospital's income for last year amounted to £13,812 and its expenditure was £15,600.

BATH EAR, NOSE, AND THROAT HOSPITAL.—This hospital celebrates its centenary next year when a special effort will be made to remove its large debt. It is hoped in the near future to undertake more preventive work among children recovering from measles and scarlet fever when the seeds of future deafness are often sown.

NOTES, COMMENTS, AND ABSTRACTS

MEALS FOR THE MILLION

At a meeting in London on March 12th, with Mr. Julian Huxley, D.Sc., in the chair, associates of the Committee against Malnutrition reported on the public food services of Soviet Russia. Mr. F. Le Gros Clark, the hon. secretary, spoke first of the efforts made to popularise the habit of feeding in restaurants and dining halls. At least five million industrial workers, he said, are now receiving one or two meals a day in the factory or public restaurants under the control of the State trusts; and this number does not include office employees or those of the collective farms, where the custom is now spreading rapidly. In earlier days no doubt most of the factory dining halls were little more than canteens; but now that is all changed, and great attention is paid to the aesthetics of dining. Comfort, brightness, and the taste of food are nowadays carefully considered, and flavouring, gravies, and mayonnaises are tested to ensure that the meals constantly improve not only in wholesomeness but in attractiveness.

In fairness to the system, said the speaker, one must prevent the British public from assuming that this social feeding implies the uncomfortable regimentation of the people. If this was granted, it was easy to see that the Soviet Union was wise in encouraging the habit of dining in restaurants; since it could thus guarantee a large proportion of the population one, two, or even three meals a day cheaply and on a diet that was certified pure and varied. It could also in this way discover and deal with the inevitable difficulties associated with the growth of a new public service, the food service. Would the people of Soviet Russia develop further this custom of dining communally or would they revert later to the habit of family meals? This, he thought, was a matter for the people themselves. But with the steady drop in food prices that was now being experienced, the argument that the restaurant meals were cheaper would be removed. One of the decisive factors that would make for the permanence of the restaurant system was the saving in time for the women; another was the conversion of the factory restaurants into comfortable clubs, of which the workers were unquestionably proud.

A further striking feature of the restaurant system was the opportunity it gave for prescribing special diets to those who required them. The science and art of cookery could ensure that these diets were palatable, while adhering strictly to the prescription. Well over half a million factory workers and others were now receiving daily diets on this basis, and figures seemed to indicate that their health was benefiting. Here, said Mr. Le Gros Clark, was the establishment of a great principle, and only by organising in the first stages some kind of communal feeding could the principle be properly tested and its results observed. Extensive studies were being made into the diets most beneficial to different occupations and in different climates. The question, for instance, of wear and tear on the human organism from work in heated conditions was being closely examined. The research was of a highly practical nature. In our own country there was a praiseworthy effort being made by a few employers to supply their young workers with extra milk. This was good, provided that low wages were not being depleted by making the young people pay for their own milk. In the Soviet Union the extra cost of the more expensive health diets referred to was met out of the social insurance funds; these, it must be noted, were on a non-contributory basis.

Enlarging on the problem of tuberculosis, the speaker said that the figures examined showed a considerable drop in mortality and loss of working days in the last few years. In Moscow the tuberculosis death-rate had risen during the civil wars

to 40 per 1000 of population; it was now less than 12, and great efforts were being made in the industrial centres to discover hitherto unsuspected cases. In this campaign the communal dining arrangements played a considerable part. It appeared that in all cases separate tables were allotted to tuberculosis patients, and in a growing number of cases separate compartments; their crockery had by regulation a distinctive pattern on it and must be kept apart.

The report which formed the basis of Mr. Le Gros Clark's address may be had from the Committee Against Malnutrition, 19c, Eagle-street, London, W.C.1. (1d., post free 2d.).

FILING OF CURRENT JOURNALS

THE weekly growing heap of periodicals is an increasing source of annoyance to anyone who has to collect and keep them for reference. He has the choice between a neat pile, useless if undisturbed, or an untidy chaos, recourse to which becomes more and more exasperating. An ingenious binding case has been devised by EASIBIND Ltd. (9, Mallow-street, London, E.C.1) which should help to solve the problem. Different covers can be obtained to fit the main medical and scientific journals and each is attractively made, bearing on the back the name and year of the publication; that for THE LANCET holds all the issues of one volume and costs 3s. 6d. net. Each issue can be inserted within half a minute. A thin wire rod is laid between the middle pages and attached by each end to the back of the cover; the whole is firmly secured by a thicker rod. The growing volume can then be placed among the other reference works on the library shelf. If desired, any particular issue can be removed in a few seconds without disturbing the others. When the case is filled it appears very little different from an ordinary bound volume.

A BISCUIT FACTORY

BISCUITS are the product of an age which has largely given up cooking for itself and likes to have its ready-cooked food elegantly served in known doses. It might be hard to say whether the demand has created the supply or vice versa. Anyhow, Peak Freans has grown in three quarters of a century from a small factory to what is known as "Biscuit Town," employing 5000 workers in 29 different trades. There are tailors, carpenters, bakers, printers, engineers, a steam laundry, an internal postal service, and a fire brigade, as well as a medical and dental service. All these play some part in the making of such a product as the wholemeal "crispbread" Vita-weat, for example. The wheat is soaked overnight and subjected to a special "gelatinising" cooking process which preserve all the constituents of the fresh grain. This is crushed to a fine pulp between granite rollers; and the other ingredients, chiefly fat, are added in a large hopper. The mass is then rolled into thin sheets which receive a heavy impression of the shape of the biscuits. These are toasted on endless belts passing through long ovens with a carefully regulated temperature. Every batch is weighed and compared with two standard biscuits for colour, there being a different degree of toasting on each side. Each biscuit is therefore of uniform composition, with a known calorific value and a high vitamin B content. They are then packed in containers made and printed in the factory.

The workers are drawn from the surrounding districts, and have to pass as physically sound, first the employment authorities, then the factory's medical officer, and finally the Home Office inspectors; all new workers are vaccinated. Their work is graded from the results of tests in manual dexterity and mental alertness, but misfits are treated sympathetically, and it is rare for a recruit once accepted to be dismissed on account of ill-health or incompetence. The health of the workers is in the charge of the

medical officer, a nurse, and two dentists, equipped with a surgery and dispensary, which is claimed to be one of the first of its kind, for it began in 1908, and a dental surgery. There were 15,000 dressings in 1935, and a record number received dental treatment. More serious conditions are referred to the patient's insurance doctor, but employees not eligible for insurance are treated in their own homes by the factory's medical officer.

A HANDBOOK OF PHOTOGRAPHY

THE photographer who, whilst not finding the need for regular perusal of a weekly journal, yet wishes to keep informed of progress and development in technique, will find the *British Journal Photographic Almanac* a convenient means of doing so. This well-known annual gives brief descriptions of new apparatus and methods of working, and a short section deals with new models of cine-projectors and cameras designed mainly for amateur use. The projectors described vary in price from £75 for a machine suitable for use in a small hall to £17 for one for home use, both being designed for use with 16 mm. film, and from £33 to 37s. 6d. for machines to take the smaller size film, the latter price applying to a hand machine. The descriptions given do not exhaust the models available, and those of our readers to whom this branch of photography appeals will be able to obtain more detailed information from dealers. The formulæ presented in the handbook are as varied and useful as ever and the whole production will be found a valuable work of reference. It is issued at 3s. (cloth) and 2s. (paper) by Henry Greenwood and Co., Ltd., 24, Wellington-street, London, W.C.2.

Appointments

BAKER, A. H. L., L.M.S.S.A. Lond., has been appointed Resident Anaesthetist at the West Middlesex County Hospital.
 COOKSON, C. C., M.B. Birm., Casualty Medical Officer at the West Middlesex County Hospital.
 GILBERT, B., M.D. Lond., F.R.C.S. Eng., M.C.O.G., Registrar and Tutor to the Obstetric Department at St. Thomas's Hospital.
 RIDLEY, N. H. L., M.B. Camb., F.R.C.S. Eng., Registrar to the Ophthalmic Department at St. Thomas's Hospital.
 SEARLE, W. N., M.B. N.Z., F.R.C.S. Edin., M.C.O.G., Registrar and Radium Officer at the Chelsea Hospital for Women.
Royal Masonic Hospital.—The following appointments are announced:—
 CRITCHLEY, MACDONALD, M.D. Brist., F.R.O.P. Lond., Neurological Physician;
 LINDSAY, E. C., M.B. Lond., F.R.C.S. Eng., Surgeon; and
 SHORTER, A. A., M.B. Sydney, Resident Surgical Officer.

Vacancies

For further information refer to the advertisement columns.

Aylesbury, Royal Buckinghamshire Hospital.—Second Res. M.O. £150.
Barnsley Municipal General Hospital.—First Asst. M.O. £650.
Belfast, Royal Victoria Hospital.—Res. Biochemist. At rate of £100.
Belgrave Hospital for Children, Clapham-road, S.W.—Two H.P.'s and one H.S. Each at rate of £100.
Birmingham City, Maternity and Child Welfare Dept.—Three Temp. M.O.'s. Each £10 per week.
Blackburn County Borough.—Asst. M.O.H. and Asst. School M.O. £600.
Bolton Royal Infirmary.—H.S. £125.
Bradford, Royal Infirmary.—H.S. At rate of £135.
Bristol, Ham Green Hospital and Sanatorium.—Jun. Asst. Res. M.O. £250.
British Postgraduate Medical School, Ducane-road, W.—Three H.S.'s.
Buxton, Derbyshire, Devonshire Royal Hospital.—Hon. Asst. Physician.
Cambridge, Addenbrooke's Hospital.—H.P. Also H.S. to Special Depts. Each at rate of £130.
Canterbury, Kent and Canterbury Hospital.—H.S. At rate of £125.
Canterbury, Kent County Mental Hospital, Chartham Down.—Med. Supt. £1000.
Cardiff, King Edward VII. Welsh National Memorial Association.—Res. Asst. Tuber. M.O. £500. Res. M.O. £350. Also Asst. Res. M.O. £200, for Sully Hospital, Glam.
Charing Cross Hospital.—Hon. Clin. Asst. to Dermatological Dept.

Chelsea Hospital for Women, Arthur-street, S.W.—Surgeon for Ear, Nose, and Throat.
Cheshire, Institution for Mental Defectives, Cranage Hall.—Res. Med. Supt. £800.
Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall.—H.P. At rate of £150.
City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.
Derby, Brebly Hall Orthopaedic Hospital, near Burton-on-Trent.—Res. H.S. £150.
Deusbury, Infectious Diseases Hospital.—Res. M.O. £200.
Durham County Council.—Asst. Welfare M.O. £500.
Eastbourne Royal Eye Hospital, Pevensey-road.—H.S. £100.
Elizabeth Garrett Anderson Hospital, 144, Euston-road, N.W.—Hon. Asst. Obstetrician.
Evelina Hospital for Sick Children, Southwark, S.E.—Dental Surgeon. Also H.S. At rate of £120.
Exeter, Royal Devon and Exeter Hospital.—H.S. to Ear, Nose, and Throat Dept. At rate of £150.
Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Res. Surg. O. £150. Also Asst. Res. M.O. and 3 H.P.'s. At rate of £150 and £50 respectively.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—Res. M.O. Also H.P. At rate of £150 and £100 respectively.
Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.—Res. H.S. At rate of £75.
Huddersfield Royal Infirmary.—Cas. O. £200.
Iford, King George Hospital.—H.P. and two H.S.'s.
Infants Hospital, Vincent-square, Westminster, S.W.—H.P. At rate of £75.
Isolation Hospital, Muswell Hill.—Res. M.O. £400.
Laboratories of Pathology and Public Health, 6, Harley-street, W.—Third Asst. Pathologist. £450.
Lancaster County Mental Hospital.—Asst. M.O. £500.
Liverpool, Broadgreen Sanatorium.—Res. Asst. M.O. £200.
London County Council.—Two Asst. M.O.'s (Grade I). Each £350. Four Asst. M.O.'s (Grade II). Each £250. Also five Temp. District M.O.'s. £300-£100. Temporary Asst. Aurist. 34s. 6d. a session.
L.C.C. Central Histological Laboratory, Archway Hospital, Archway-road, N.—Asst. Pathologist. £650.
London Lock Hospitals.—Two Res. M.O.'s. One for Male Dept. One for Female Dept. Each at rate of £175.
London (R.F.H.) School of Medicine for Women, 8, Hunter-street, W.C.—Post-graduate Scholarships. Each £200.
Macclesfield General Infirmary.—Second H.S. At rate of £150.
Maidstone, Kent County Ophthalmic and Aural Hospital.—Ophth. H.S. At rate of £200.
Manchester Royal Eye Hospital.—Jun. H.S. £120.
Mount Vernon Hospital, Northwood.—Asst. Radiologist. £350.
Newport, Mon., Royal Gwent Hospital.—Cas. O. At rate of £175.
Paddington Green Children's Hospital, W.—H.P. and H.S. Each at rate of £150.
Port Said, British Hospital.—Principal M.O. £700.
Princess Beatrice Hospital, Earl's Court, S.W.—Hon. Anaesthetist.
Queen Mary's Hospital for the East End, Stratford, E.—Asst. Radiologist. £150. Also Obstet. H.S. £120.
Reading, Royal Berkshire Hospital.—H.P. Also Cas. O. Each at rate of £125.
Redhill, Royal Earlswood Institution.—Jun. Asst. M.O. At rate of £250.
Richmond, Surrey Royal Hospital.—Jun. H.S. At rate of £100.
Rochdale Infirmary and Dispensary.—Second H.S. £150.
Rotherham Hospital.—Cas. H.S. £150.
Rotherham, Oakwood Hall Sanatorium.—Asst. Res. M.O. £250.
Royal Free Hospital, Gray's Inn-road, W.C.—Res. Cas. O. At rate of £150.
Royal National Orthopaedic Hospital, 234, Great Portland-street, W.—H.S. At rate of £150.
Royal Northern Hospital.—Asst. Pathologist. £500.
Royal Waterloo Hospital for Children and Women, S.E.—Hon. Asst. Orthopaedic Surgeon.
St. Mary's Hospital, W.—Med. Reg. £200.
Salford, Hope Hospital.—Res. Obstet. Officer. £400.
Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. At rate of £100.
Sidmouth U.D.C.—M.O.H. £260.
Southeast-on-Sea General Hospital.—Two H.S.'s. Each at rate of £100.
South Mimms, County (Tuberculosis) Sanatorium, Clare Hall.—Deputy Med. Supt. £400.
Swanley Hospital Convalescent Home, Parkwood.—Res. M.O. At rate of £200.
Torquay, Torbay Hospital.—H.S. £175.
University College Hospital Medical School, W.C.—Jun. Fellows for Beit Memorial Fellowships. Each £400.
Walsall General Hospital.—H.P. and Res. Asst. Pathologist. At rate of £150. Also H.S. £150.
Walsall, Manor Hospital.—Jun. Res. Asst. M.O. £150.
Warrington Infirmary and Dispensary.—Third Resident. At rate of £150.
Warwick, King Edward VII. Memorial Sanatorium, Hertford Hill.—Jun. Asst. M.O. At rate of £250.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. and Jun. Res. H.S.'s. At rate of £150 and £100 respectively.
West London Hospital, Hammersmith-road, W.—Physician.
Wigan, Royal Albert Edward Infirmary and Dispensary.—Res. Med. and Surg. O. and Reg. £250. Also H.S. At rate of £150.
Willesden General Hospital, Harlesden-road, N.W.—Hon. Anaesthetist.
Wrexham and East Denbighshire War Memorial Hospital.—Res. H.S. At rate of £150.
Yorkshire Children's Orthopaedic Hospital, Kirbymoorside.—H.S. £200.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Knottingley and Hoyland Nether (Yorks, W.R.); and Stirling (Stirling).

ADDRESSES AND ORIGINAL ARTICLES

ON CERTAIN SEPTICÆMIAS
DUE TO ANAEROBIC ORGANISMS *

By A. LEMIERRE, M.D.

PROFESSOR OF BACTERIOLOGY IN THE FACULTY OF MEDICINE,
PARIS; PHYSICIAN TO THE CLAUDE BERNARD HOSPITAL

THE septicæmias dealt with in this address arise from several species of anaerobic organisms which are specifically distinct from one another but which possess the common character of living as saprophytes in the natural cavities of the human body, mouth, pharynx, intestine, and genito-urinary passages; they are fragile, very slightly motile, and grow sparsely on culture media. To this group of organisms belong those Gram-negative and non-spore bearing bacilli which certain bacteriologists group together under the name of "bacteroides"; their rôle in the production of non-traumatic gangrene has been described in France by Veillon, Zuber, Rist, Guillemot, and Hallé. With them must also be placed certain Gram-positive anaerobic micrococci, streptococci, and staphylococci, which have been variously named by the different authors describing them.

These septicæmias arise from inflammatory or suppurative lesions in the tissues or cavities where the above-mentioned anaerobic organisms exist under physiological conditions. Having proliferated in these localities they pass into the blood stream and frequently give rise to septic emboli in distant areas. Such septicæmias tend to arise—

- (1) From inflammatory lesions of the nasopharynx, particularly tonsillar and peritonsillar abscesses.
- (2) From similar lesions of the mouth and jaws.
- (3) In connexion with otitis media or mastoiditis.
- (4) From purulent endometritis following parturition.
- (5) From appendicitis.
- (6) From infections of the urinary passages.

But whatever their origin, they present certain common clinical aspects which enable them to be grouped together. For that reason, as typical of the group as a whole, the post-anginal septicæmias will be first described, and in later portions of this paper attention will be directed to the clinical and pathological similarity between such post-anginal septicæmias and those which arise from other sites.

The post-anginal septicæmias due to anaerobic organisms most frequently seen in Paris are due particularly to the *Bacillus funduliformis*, described in 1898 by Jean Hallé, which can usually be isolated in pure culture from the blood and from secondary abscesses; it is sometimes associated with an anaerobic streptococcus. The first cases of septicæmia from this cause were described in 1929 and 1931 by Prof. Pierre Teissier and his collaborators Jean Reilly, Rivalier, Layani, and Stefanescu; later similar observations were published by the writer with Jean Reilly, Layani, Friedman, and André Meyer, by Cathala, Bourgeois, and Gabriel, by Jame and Jaulmes, and by P. de Font-Réaulx. In 1935 Pham Huu-Chi published a considerable work on this subject.

In Germany, where Schottmüller must be given the credit of being the first to describe them in 1918, the importance of the anaerobic post-anginal septicæmias has been emphasised by a number of

physicians, including Buigold, Fränkel, Claus, and Kissling. The name given by them to the usual causal organism of such septicæmias is *Bacillus symbiophiles*, and they state that it is usually associated with an anaerobic streptococcus. The present uncertainty concerning the classification of anaerobic organisms and the diversity of bacteriological tests employed by different observers to identify them make it possible that *B. funduliformis* and *B. symbiophiles* are either identical or else belong to very similar species of bacteria. In any case the description which the German authorities give of the post-anginal septicæmias corresponds feature by feature to what the present writer has observed.

Clinical Picture

The disease usually affects young adults or adolescents, both sexes being equally attacked. Claus and Kissling have observed that sometimes small epidemics occur, a fact which I can confirm. The most usual initial cause is a tonsillar or peritonsillar abscess, opened too late or to an insufficient degree. At times what appears to be a simple tonsillitis may conceal small foci of suppuration in the depths of the tissues which cannot be demonstrated clinically; an example of this was recently under my observation at the Claude Bernard Hospital in Paris.

Since the original work of E. Fränkel in 1919 German authorities have considered that these septicæmias are the result of a thrombophlebitis of the tonsillar and peritonsillar veins which can spread to the internal jugular vein or even to the facial vein. My own observations agree with this conception.

The first symptom of septicæmia complicating the pharyngeal inflammation is a notable rise of temperature to 101° or 103° F., accompanied by an intense rigor. The rigor usually occurs on the fourth or fifth day after the beginning of the sore-throat, occasionally as late as the eighth, tenth, or even twelfth day, by which time the tonsillar inflammation appears to be cured and the initial fever has disappeared. After this rigors are repeated daily, several times per day, or at more remote intervals. In the gravest cases the temperature remains in the region of 100° to 103° with exacerbations corresponding to the rigors; in milder and more chronic cases the pyrexia is hectic and irregular.

There is usually painful swelling of the glands below the maxillary angle usually on one side only, occasionally on both; there is slight local œdema and tenderness on pressure and on movement of the head; this occurs on the lateral aspects of the neck, parallel to the sternomastoid muscle, and extends from the angle of the jaw to the clavicle; suppuration sometimes occurs at this site.

The *B. funduliformis* septicæmias observed by myself have never been pure septicæmias, they have always been accompanied by the formation of distant metastatic abscesses. Amongst such secondary localisations the most frequent are those in the lungs. They occur early and may be present from the first day. They are in the nature of septic infarcts leading almost invariably to multiple abscess formation which is announced by intense thoracic pain of sudden onset, by dyspnoea, sometimes by blood-stained or rusty sputum, by pleural frictions, and by localised areas of subcrepitant râles. Very frequently these pulmonary infarcts are complicated by purulent pleural effusions containing *B. funduliformis*, but in

* An address delivered on March 3rd, 1936, at the Middlesex Hospital Medical School.
5874

rare cases such effusions may be serofibrinous and aseptic. These purulent effusions occasionally open spontaneously into a bronchus, giving rise to a pyopneumothorax.

Articular lesions are also extremely frequent; they range from simple pains in the joints, sometimes of great severity, to suppurative arthritis occurring especially in the shoulders, elbows, knees, sternoclavicular or sacroiliac articulations.

Icterus and subicterus have often been noted and urobilin is invariably present in considerable quantities in the urine.

Renal lesions are manifested by albuminuria, sometimes accompanied by a slight or considerable increase in the blood-urea. I have also had occasion to observe thyroiditis, suppurative peritonitis, abscess formation in the psoas muscle or in the deep muscles of the buttock originating from sacroiliac arthritis. During the course of the disease there is usually a leucocytosis ranging from 13,000 to 30,000 white cells and in the more chronic cases the red cells are sometimes reduced to 2 or 3 millions.

These septicæmias may progress rapidly and end fatally in from 7 to 15 days; in such cases the temperature remains constantly high, the patient is in a state of extreme prostration with the aspect of a case of typhus, and dies in coma. In other cases the repeated recurrence of attacks of extreme high temperature may in a few days bring about fatal collapse. Again the fatal termination may be delayed to the end of the third week, or even a month or six weeks may pass before it occurs. In such examples the temperature becomes irregular and oscillating; in accordance with the recurrence of excessive febrile attacks one sees the usual phenomena appear; pulmonary infarcts, pleural effusions, and arthritic phenomena; the patient wastes, the colour becomes pale and earthy, and there are profuse sweats; finally delirium occurs and death follows in a condition of cachexia. It may be hastened by the sudden bursting of an abscess into the bronchus followed by syncope.

Diagnosis

The most characteristic lesions found at autopsy are those in the respiratory tract. The lungs are the site of necrotic infarcts, both centrally and peripherally, usually about the size of a pigeon's egg and circumscribed. Some are seen as yellow masses surrounded by a hæmorrhagic zone, others in the form of cavities containing pus. From these lesions *B. funduliformis* can usually be recovered in pure culture, but occasionally it is associated with an anaerobic streptococcus. In a case recorded by Prof. Tessier and his co-workers, which was accompanied by deep jaundice and purpura, the liver was greatly enlarged and was studded with necrotic abscesses from which the organism was isolated in pure state.

From this it is clear that these septicæmias carry an extremely grave prognosis. Of the 20 cases observed by the writer and certain of his colleagues in Paris only two have recovered. These two were, however, amongst those appearing most ill and were complicated by pulmonary and arthritic manifestations; further, the number of organisms in the blood, estimated after the examinations of cultures, appeared as great in these as in the fatal cases. In these survivors cure occurred spontaneously and treatment had been of purely symptomatic character.

It is therefore understandable that certain German observers have been led, as soon as the clinical diagnosis was possible, and without awaiting the

results of bacteriological examination, to perform ligation of the internal jugular vein on the side of the affected tonsil. They claim that thanks to this intervention the mortality has been diminished. I have personally had recourse to this treatment in a recent case but unhappily without success in preventing a fatal termination.

To anyone instructed as to the nature of these septicæmias it becomes relatively easy to make a diagnosis on the simple clinical findings. The appearance and repetition several days after the onset of a sore-throat (and particularly of a tonsillar abscess) of severe pyrexial attacks with an initial rigor, or still more certainly the occurrence of pulmonary infarcts and arthritic manifestations, constitute a syndrome so characteristic that mistake is almost impossible.

Certain diagnosis is established by bacteriological examination. *B. funduliformis* is easy to discover in the purulent effusions, but it is blood culture on anaerobic media which gives the earliest definite information, and this is particularly sure if the blood is taken during a rigor.

The culture medium employed at the Claude Bernard Hospital by J. Reilly, which can be particularly recommended, consists of 10 c.cm. of the glucose agar of Veillon to which is added 40 c.cm. of peptonised bouillon and 2 c.cm. of a 20 per cent. solution of glucose. This medium divided in glass tubes 25 cm. long and 25 mm. wide, is liquefied by heat at the moment of employment and kept at a temperature of 40°C. After 2 to 4 c.cm. of blood have been added the tubes are immediately cooled under the tap. The colonies appear in it after two to four days' incubation at 37°.

B. funduliformis in pus smears appears in the form of a fine bacillus of 2 to 3 μ in length, Gram-negative, and exhibiting at each end a well-coloured mass, whilst the centre of the microbe remains clear. In cultures it presents, and this is a very important point, a remarkable polymorphic appearance. It occurs in preparations simultaneously as a fine bacillus, as long filaments, more or less voluminous, and sometimes as spherical elements. Some of these spherical bodies, of a diameter of about 2 to 4 μ , are intensely susceptible to basic stains. Others achieve greater dimensions, as much as 12 to 14 μ . Their protoplasm is clear but they contain coloured nuclei of various shapes sometimes resembling the nuclei of polynuclear leucocytes. The spherical elements are quite characteristic and permit absolute identification of *B. funduliformis*. The polymorphic character of the microbe elements may be observed in the first cultures obtained from the blood but is much more obvious in subcultures. In individual cases sometimes the forms with filaments and sometimes the spherical forms predominate.

One further characteristic of the bacillus may be mentioned—namely, that it is constantly hæmolytic. Finally, J. Reilly has demonstrated that, on injection of cultures into the rabbit, septicæmia with metastatic abscess formation in the lungs, liver, and joints, exactly comparable to what is seen in man, is produced.

Various Sites of Infection

THROAT AND EAR

The *B. funduliformis* is the commonest pathogenic agent in post-anginal septicæmias such as have been described above. But other bacilli of the same group may also be the causal agents. Allusion has already been made to the *B. symbiophiles* of Schottmüller; recently Grumbach and Verdan (of Zürich) have in three instances found in the blood a "fuso-bacterium nucleatum" which is perhaps identical with *B. funduliformis*. There is, on the other hand, an anaerobic organism very definitely distinct from *B. funduliformis*—namely, *B. fragilis*—which is occasionally

responsible, as the present writer, with Guy and Rudolph, has demonstrated; a similar infection has been observed by Richon, Kissel, and Lepoire.

The infections described above are marked by rigors and embolic phenomena, but it occasionally happens that somewhat similar fevers are observed which get well without any such complications although blood culture has revealed anaerobic organisms; we have, for example, observed cases of this sort from which *B. ramosus* has been recovered and another due to an anaerobic staphylococcus. Such cases are exceptional and are not due to a true septicæmia but to simple momentary and benign bacteræmia. These observations are nevertheless instructive; the transient discharge of organisms into the blood stream during a pharyngeal infection is certainly capable, occasionally, of producing embolic phenomena which may take on the appearance of a local disease in which the original cause is not clear. Such septic emboli may be the origin of certain cases of pulmonary suppuration or of empyema or arthritis, clinically resembling that which has been described in this paper but of lesser gravity because a true septicæmia is not present.

On the other hand, the reason why the complications heretofore described have been straightforward suppuration, but not of a putrefactive character, is that they have been due to pure infection by *B. funduliformis* or at most to this organism associated with an anaerobic streptococcus. The fœtid pus of tonsillar abscesses contains many species of anaerobic organisms, and it is surprising that only one or two of them usually pass into the blood stream. It does, however, occasionally occur that others of these anaerobes may take this course and give rise to septicæmias of mixed origin with putrid embolic foci. I have, for example, described with P. de Font-Réaulx, a case with the usual blood picture but complicated by gangrenous osteoperibstitis of the pubis and gangrenous pulmonary abscesses containing many different species of anaerobic organisms.

The description given of the post-anginal septicæmias is sufficient to allow review of those arising from other primary foci to be very brief. Such are observed in the course of otitis and mastoiditis particularly when fœtid otorrhœa has been present, such fœtor being due to infection with anaerobes. Otitis of this type is very frequently complicated by lateral sinus thrombosis and is the cause of pulmonary emboli.

Anaerobic septicæmia arising from otitis and proved by blood culture has been described particularly by Guillemot (*B. fragilis* and *B. radiiformis*), by Boez, Keller, and Kehlstadt (*B. fragilis*), by Boez, Keller, and Schreiber (*B. ramosus*), by Langeron (anaerobic staphylococcus), and by Franklin and Camb (Gram-negative *B. fusiformis*).

The clinical manifestations of such septicæmias are very closely similar to the picture given of the post-anginal septicæmias. The same picture has been observed by us in connexion with buccal suppuration following the extraction of heavily infected teeth.

UTERUS AND PELVIC ORGANS

Anaerobic septicæmias are well known as complications of postpartum uterine sepsis. The clinical similarity of these to the post-anginal septicæmias has recently been emphasised by A. Schneider. The normal presence of *B. funduliformis* and other anaerobic organisms in the vagina was noted in 1898 by J. Hallé, and in 1902 Jeannin called attention to the proliferation of these anaerobes in the uterine cavity after any severe case of suppurative puerperal endometritis.

In a series of publications since 1910, Schottmüller has given a full description of these septicæmias which are always linked with the presence of peri-uterine thrombophlebitis; fever, repeated rigors, pulmonary metastases, and occasional icterus are the outstanding clinical features. He gives as the commonest cause an anaerobic streptococcus, the *Streptococcus putridus*, which may be associated with other organisms including the *B. symbiophiles*. Similar cases have been observed by myself and by Boez, Keller, and Kehlstadt. In the uterine septicæmias, as in the post-anginal ones, the metastatic abscesses are only fœtid when the infection includes a number of different species of anaerobes.

It has further been noted that similar phenomena may occur after surgical operations on the uterus and pelvic organs, and that apart from septicæmia a simple bacteræmia may occur producing distant abscesses the primary focus of which may be overlooked.

OTHER LOCI

Gangrenous appendicitis is known to arise frequently from anaerobic infections; such cases are sometimes complicated by thrombophlebitis of the mesenteric veins, by pyelphlebitis, by liver abscess, and by fœtid subphrenic abscess. In such cases Schottmüller has isolated from the blood streptococci, anaerobic staphylococci, and the *B. symbiophiles*. Nedelmann has recently isolated the last-named from such a case in pure culture. The site of the thrombophlebitis in such cases prohibits the formation of pulmonary infarcts, but gangrene of the lung and purulent pleurisy are occasional complications. The usual high fever and rigors characterise such cases.

In 1899 Cottet noted the presence of organisms of this type, notably *B. funduliformis*, in certain cases of peri-urethral suppuration. Thomson and Beaver have reported a case of septicæmia due to *B. fragilis* in a patient suffering from cancer of the bladder, and another of septicæmia due to *B. funduliformis* following prostatectomy, this last case being complicated by iliac phlebitis and pulmonary metastases.

Summary

No attempt has been made to review completely the literature of the subject, but sufficient has been said to demonstrate that, whatever their primary focus, the septicæmias produced by the anaerobic organisms which occur as saprophytes in the natural cavities of the human body display remarkable clinical similarities. They commence by suppuration in the local site and this is followed by local thrombophlebitis. Considerable fever and intense rigors are the next feature, and these are followed very frequently by septic pulmonary emboli. The syndrome is so characteristic that it permits of diagnosis before bacteriological examination, including blood culture, has provided conclusive proof. The post-anginal septicæmias due to *B. funduliformis* have been specially described, but the same phenomena are observed when such septicæmias of anaerobic origin arise from other initial causes.

II.—SODIUM DEFICIENCIES IN CLINICAL MEDICINE

The Body Fluids

At the outset of this lecture I wish to say something of the formation and composition of the body fluids, a number of which are set out in diagrammatic fashion in the accompanying Figure. The upper half of each rectangle represents, in milli-equivalents per litre, the concentrations of the bases in that fluid, and the lower half indicates the concentrations of the acids. For any given fluid the two must obviously be equal. It will be noticed that the composition of the cell fluid differs radically from that of all extracellular fluids, for the former contains chiefly potassium phosphate whereas the latter characteristically contain sodium chloride and bicarbonate. There is practically no interchange of basic ions between the cells and the fluids surrounding them.

The substances dissolved in these fluids cause them to have a considerable osmotic pressure which amounts to about 8 atmospheres.²⁶⁷ The pressure is due (a) to the non-electrolytes. In man these contribute only a small quota to the total osmotic pressure and are not indicated in the diagram. They are, generally speaking, equally distributed between cells and plasma, and so merely raise or lower the general level of osmotic pressure of the whole body without affecting the water distribution between the cells and plasma. In the dogfish non-electrolytes are present throughout the body in large amounts and so raise its osmotic pressure above that of the surrounding sea water. We were chiefly concerned with this total osmotic pressure of the body in the discussion of the water regulation of the marine fish (Lecture I.). (b) To the electrolytes. These consist of the inorganic and organic (protein) ions, but the inorganic ions give rise to nearly the whole of the electrolytic osmotic pressure. The protein ions contribute so little towards it that they may almost be neglected, and therefore the electrolytic osmotic pressure taken to be the sum of the osmotic pressures due to the inorganic basic and acidic ions. Since the basic ions of the extracellular and cellular fluids are not interchangeable, their concentrations control the electrolytic osmotic pressure of their respective fluids, and hence the water distribution between the cells and plasma. It is the electrolytic rather than the total osmotic pressure with which we are chiefly concerned in man.

The rectangles in the diagram are not all of the same length. The greater length of some of them (serum, cell fluid, semen, and bile) is due to the proteins or colloidal bile acids which they contain, and does not indicate a greater osmotic pressure.²⁶² Actually the total osmotic pressure of the serum, the other internal extracellular fluids, and of the cells are all the same. This is an important point, and indeed it is fairly certain that no fluid could remain

long in contact with the internal body cells without coming into osmotic equilibrium with them by the passage of water in one direction or the other. Even the bile in the gall-bladder, which may contain much more sodium than the serum,⁹⁰ seems to have the same osmotic pressure as the other body fluids.²⁶⁴ There is practically no protein in any of the secreted fluids, and the short rectangles (saliva and sweat) indicate real differences of osmotic pressure. These fluids which are secreted on to an impermeable stratified epithelium need not have the same osmotic pressure as the internal fluids.

With two exceptions sodium forms about 94 per cent. of the total base of the extracellular fluids. The first exception is the gastric juice, where, as is well known, hydrogen forms between 60 and 70 per cent. of the total base. The second exception is the semen, in which potassium forms 17 per cent. of the total base instead of the usual 3 per cent. The two important acid radicles of serum, oedema, cerebro-spinal fluids, and of the gastro-intestinal secretions are chlorides and bicarbonates, but they differ very greatly in their relative concentrations, and it is these differences which impart some of the peculiar characteristics to each fluid. Semen has a most interesting and unusual composition for an extracellular fluid, for it contains a large amount of phosphoric acid. The main acid radicle of sweat is chloride, but some bicarbonate, lactate, and other ions are also present.

A glance at the diagram is sufficient to show that, although the gastro-intestinal fluids and semen have the same osmotic pressure as the serum,^{99 100 101} they are true secretions in that their ionic pattern is

different. The same is true of saliva and sweat, which differ obviously from serum not only in composition but also in osmotic pressure. It is impossible to draw any accurate conclusions about the cerebro-spinal fluid from the rough diagram shown here,³ but its composition, together with that of serum, serum ultrafiltrates, and oedema fluids, is set out in Table I. The osmotic pressure of serum and cerebro-spinal fluid is the same.⁸⁶ The relative concentrations of²⁶

Succus entericus	3000	Pregl.
Approximate total	8000	—

magnesium, potassium, chloride, bicarbonate, phosphate, and sulphate in effusions, ultrafiltrates, and cerebro-spinal fluid show however that while effusions and oedema fluids are probably formed by simple ultrafiltration, the cerebro-spinal fluid is a secretion. If further evidence were required, it has been shown that large pathological variations in the serum calcium are not reflected in the cerebro-spinal fluid.^{95 106 144 216 326 332} I have, for example, recently seen two cases of severe long drawn out tetany, in which the sera contained 5.81 and 3.78 mg. of calcium per 100 c.cm. The cerebro-spinal fluids contained 5.07 and 4.36 mg. per 100 c.cm. respectively—normal amounts, and one of them actually higher than the corresponding serum.¹⁸⁷ Again, induced changes in the plasma bicarbonate only appear in the cerebro-spinal fluid if the meninges are inflamed.³¹⁸ Non-electrolytes have not the distribution between the two fluids that one would expect were the cerebro-spinal fluid an ultrafiltrate.^{46 50 60 75 266 278 327}

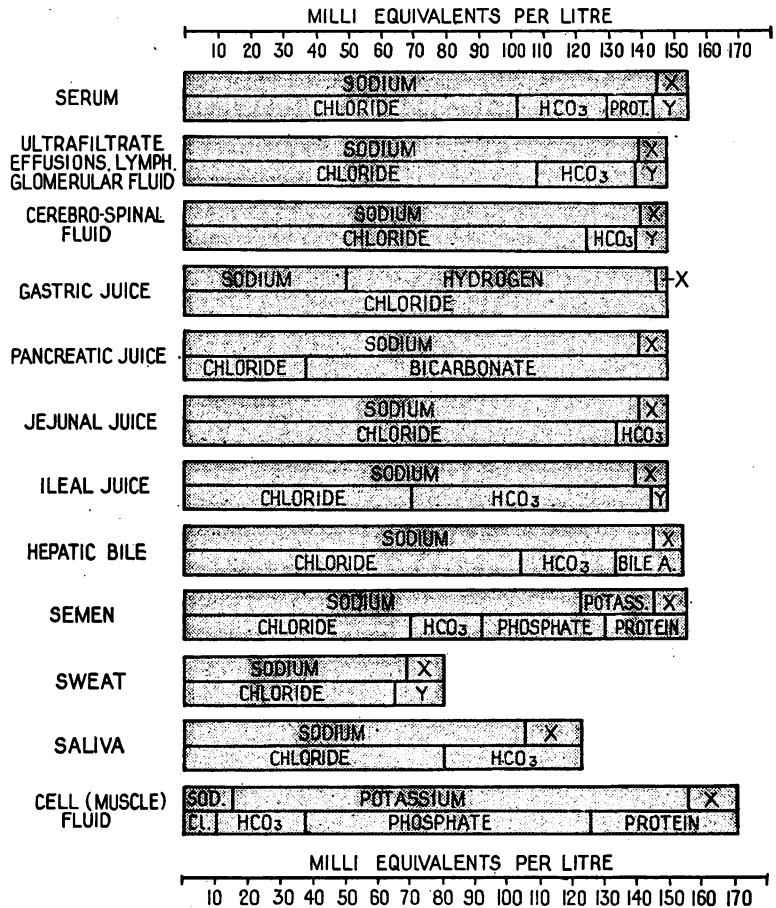

The concentration of magnesium¹⁹⁰ and possibly of chlorides^{178 181} has been found to fall in tuberculous meningitis with no corresponding change in the serum. Lastly, the way in which the flow of cerebro-spinal fluid responds to changes of oxygen and CO₂ tension strongly suggests secretion rather than filtration.²³⁶ I have perhaps over-stressed the way in which the cerebro-spinal fluid is formed, but it is not generally appreciated in this country and I think it is helpful to bring this fluid into line with others which are secreted into the body spaces.

The volume of blood in an adult's body may be taken roughly to be about 5 litres, of which say 2.5 are plasma. From this plasma all the extracellular secretions of the body are derived, and the volume of these is very large. Table II., which is copied from Rowntree²⁷³ and McQuarrie,¹⁹⁸ gives an indication of the large volumes of digestive juices which may be secreted by an adult man in 24 hours. I do not, however, think these figures unreasonably large, for Katsch and Mellinghoff^{167 215} have

obtained figures of the same order from patients from whom continuous removal of gastric juice was being practised for therapeutic reasons. It is obvious that secretion into the gut at this rate is only made possible by an equally rapid reabsorption at a lower level, and that the continuous loss of any one of the gastro-intestinal fluids must have very serious consequences because of the loss of sodium and water which it entails. I wish now to consider this subject in more detail, with special reference to the resulting sodium deficiencies.

Forced Loss of the Extracellular Fluids

(a) *Loss of the intestinal secretions.*—This is a common cause of sodium deficiency and water loss which operates in continuous vomiting,^{218 219 263 312} particularly in pregnancy,^{68 113 126 127 163 168 247 284 325} or the so-called cyclical vomiting of children,^{20 140 165} pyloric stenosis^{36 148 230 246 260} and intestinal obstruction,^{114 117 168 202 203 214 240 258} gastro-enteritis, diarrhoea and cholera,^{176 217 260 269 270 281 282 286 287} and especially perhaps in the acute diarrhoea and vomiting of children.^{45 52 131} A typical sodium chloride

deficiency has been produced by draining a gall-bladder which contained a salt-secreting papilloma.¹⁶² Our present knowledge of the subject is the result of a great deal of research and investigation commencing over one hundred years ago into the nature of the fluids lost and the resulting acid-base-water balance of the organism.^{241 242 286 287} Intestinal obstruction, 7 10 58 79 84 91 92 107 111 112 115 116 118 119 120 121 122 142 152 186 305 331 336 337 339 the continuous loss of gastric, 4 64 72 89 107 136 157 180 215 329 341 pancreatic,^{64 77 90 136} duodenal, 34 89 90 330 and intestinal juices^{16 145 150} have all been experimentally produced and the blood chemistry fully investigated. The subject has been reviewed by a number of writers.^{35 58 88 94 168 196 204 283 339}

(b) *Loss of sweat.*—This is not nearly such a common cause of sodium chloride deficiency in this country, but it may give rise to unrecognised ill-health in hot climates,^{193 194} and may be most serious^{164 195 314} or fatal. Some remarkable escapes have been recorded.¹⁹⁵ Sweating is an essential step in the production of stoker's or miner's cramp,^{67 229} and some aspects of the subject have been investigated experimentally in man.^{15 30 69 170 200 201 209 229 313 340} Small laboratory animals do not sweat. The horse does, freely, but I am not aware of any experiments on this animal.

(c) *Loss of other extracellular fluids.*—Porges and Mach have described an unusual cause of salt deficiency—namely, repeated tapping of collections of ascitic fluid in a patient who was on a low salt diet. This must be rare, but a similar method has been employed experimentally.^{63 98 161 245 291 344} Large injections of a glucose solution were made into the peritoneal cavity. The injected fluid rapidly came into equilibrium with the plasma electrolytes. By tapping the abdomen after this had taken place and before the fluid was absorbed a large part of the body's extracellular ions was removed.

Changes in the Blood and Cells Caused by the Loss of the Extracellular Fluids

Let us once more consider for a moment the composition of the body fluids and consider what will be the effect of their removal upon the fluids left behind. Take, for example, a mixture of the jejunal and ileal juices and let us suppose that 500 c.cm. have been secreted and removed from 2500 c.cm. of plasma. The mixed juices resemble plasma in composition (see Figure) except that they contain less protein, and we may consider for this purpose that 500 c.cm. of protein-free plasma have been removed. The results will be (a) a reduction in plasma volume from 2500 to 2000 c.cm.; (b) a reduction in the blood volume from say 5000 c.cm. to 4500 c.cm. and a corresponding rise in the cell count; (c) a concentration of the plasma proteins by 20 per cent. and a rise therefore in the colloidal osmotic pressure; (d) no change in the concentration of serum electrolytes—i.e., little or no change in the total osmotic pressure.

The removal of a similar volume of pancreatic juice would have brought about the same haemoco-concentration, but in other ways the results would have been different, for much more bicarbonate than chloride would have been removed. An excess of the latter therefore would have been left behind and this would have led to an acidosis. With the removal of gastric juice a still further complication would be introduced, for this juice is not only acid but contains far less sodium and more chloride than the plasma. The removal of 500 c.cm., therefore, would leave the remaining 2000 c.cm. of plasma with a deficiency of chloride but with an excess of sodium. This would

make the plasma hypertonic, but this might not be appreciable because water would move in compensation from the cells to the plasma. There would, however, be an alkalosis. 500 c.cm. of sweat contain very much less sodium chloride and bicarbonate than a similar amount of plasma. It is obvious that their removal from 2500 c.cm. of plasma would raise the concentration of sodium salts in the remaining 2000 c.cm.

In practice the removal of 500 c.cm. of one of the extracellular fluids would not greatly alter the composition of the plasma, for there are small accumulations of extracellular fluid in various parts of the body which may be drawn upon to maintain the composition of the plasma relatively unaltered. Indeed, the total amount of extracellular fluids in the body is thought to be as much as 20 per cent. of the body-weight.^{63 173} Moreover, changes in the acid-base balance may be masked by the kidney, which always tends to counteract such abnormalities. Further, water may be taken by mouth and some or all of it absorbed. After moderate loss of gastric juice or sweat this is wholly beneficial, for the water is used to restore the hypertonic plasma to normal and at the same time to make up the plasma volume. When water is absorbed after large amounts of other body fluids have been lost, or if the loss of base (however brought about) has been sufficiently severe, the osmotic pressure of the plasma is no longer strictly maintained. A compromise is struck between the volume of the plasma and its osmotic pressure,

TABLE III

so that we find them both to be reduced. In clinical medicine, and experimental work dealing with intestinal obstruction, the matter is further complicated by the fact that mixed secretions are often lost, so that the final blood picture may be more or less confused. Table III. shows the sort of changes that we might expect to find clinically in the blood. The figures, which are shown in relation to a standard normal, were not taken from particular instances but compiled from the literature and correspond to the textbook disease rather than the bedside case. It must be emphasised that the normal itself is some variation, and that patients may have secondary anaemia or a subnormal protein concentration in their plasma before the onset of acute intestinal disaster. Disregarding these complications it will be observed—

In clinical medicine, and experimental work dealing with intestinal obstruction, the matter is further complicated by the fact that mixed secretions are often lost, so that the final blood picture may be more or less confused. Table III. shows the sort of changes that we might expect to find clinically in the blood. The figures, which are shown in relation to a standard normal, were not taken from particular instances but compiled from the literature and correspond to the textbook disease rather than the bedside case. It must be emphasised that the normal itself is some variation, and that patients may have secondary anaemia or a subnormal protein concentration in their plasma before the onset of acute intestinal disaster. Disregarding these complications it will be observed—

(a) That there is always a reduction of blood volume. This is of course entirely due to a reduction in plasma volume which is also reflected in—

volume. This is of course entirely due to a reduction in plasma volume which is also reflected in—

(b) the rise of the red cell count and

(c) the rise in the plasma proteins.

(d) There is a fall in the serum sodium, except when sweating has been severe and water has not been taken by mouth. It is not invariable in pyloric stenosis, for reasons which I have just given, but usual. In assessing the total loss of sodium from the body, both the reduction in the extracellular fluid volume and in the concentration of sodium in these fluids must be considered.

(e) There is a fall of chloride and rise of bicarbonate in pyloric stenosis due to the loss of hydrochloric acid in the vomit. In diarrhoea, in which the alkaline pancreatic juices are lost, the fall in bicarbonate exceeds the fall in chloride.

(f) In intestinal obstruction there may be a simultaneous loss of pancreatic and gastric juices so that there may be little or no change in the acid-base balance of the plasma.

(g) A rise in the blood-urea always accompanies these changes. This will be referred to later.

Since the osmotic pressure of the cells is always close to that of the plasma, you will appreciate that these departures from the normal electrolyte pattern of the plasma must affect the cells. A rise or fall in the concentration of sodium alters the electrolytic osmotic pressure of the plasma, and the cells of the solid tissue conform to this by varying their water content. They do not lose potassium^{224 248} or take up sodium. The red blood-cells of man behave like the tissue cells. The erythrocytes of the dog, on the other hand, which contain sodium but not potassium respond to osmotic changes in their environment by changing their base rather than their water content.²⁴⁴

The Chemical Pathology of Addison's Disease

I turn now to other causes of sodium and water deficiency and say something of Addison's disease. Clinically, the progressive destruction of the suprarenal is accompanied by widespread symptoms and signs,^{129 274 275 292} but notably by a low blood pressure, wasting, asthenia, pigmentation, urea retention, anorexia, and often vomiting. The serum sodium is abnormally low, but this is not the result of the vomiting. The chemical pathology of this disease has been enormously advanced by the experimental suprarenalectomies which have been carried out extensively on rats, cats, and dogs in the last few years. Blood pressures have been found to fall in rats⁷⁴ and dogs,^{245 311} and the animals become very weak and die before long unless treatment is administered. The blood changes have been studied^{13 14 37 38 183 185 208 291 305 308 320 345 346} on numerous occasions, and it has been established that the blood volumes fall and the red cell counts increase. Polycythæmia is not a feature of the clinical disease because it may be obscured by a secondary anæmia,^{274 275} or a compensatory reduction of red cells.^{128 211} The disease is so chronic that there is ample time for such secondary adjustments to take place. The hæmoglobin, however, has been observed to fall with the administration of sodium chloride and to rise again when salt was withheld.¹⁴⁹ The serum proteins rise,^{185 308} but curiously enough Silvette and Britton²⁹¹ did not find this in cats and I think the matter should be further investigated. The only patient with Addison's disease whose serum I have had the opportunity of examining had over 7 per cent. of serum proteins. This is normal, but in my experience it is higher than one would expect in a chronic wasting disease. The explanation is to be found in the work of Greene et al.¹⁰⁸ on the clinical disease. These authors have found that the serum proteins may be normal when the patients are in good condition, but that in the periods of crisis they are raised. All are agreed that after bilateral suprarenalectomy the serum

sodium falls and with it the chloride^{185 345} and, to some extent, the alkali reserve.¹⁸³ These changes reduce the electrolytic osmotic pressure of the plasma. Hence the normal distribution of water between the cells and plasma is upset, for the muscles, which do not lose their electrolytes, take up water^{289 290} till osmotic equilibrium is restored. Marañon and Collazo²⁰⁸ have not confirmed this over-hydration of the muscles on clinical material, but their evidence on this point is unsatisfactory because it is not clear how they obtained their controls. The blood-sugar falls,^{37 38 289} the serum potassium rises,^{208 320 346} and there may be some interference with the absorption of fat from the intestine.^{323 324} The blood-urea rises. It will be seen that the changes in plasma volume, blood volume, cell count, serum sodium, chloride and urea are the same as those which occur when sweating is severe and accompanied by the ingestion of large amounts of water—i.e., in sodium chloride deficiency without water deprivation (Table III.)—and the primary cause I consider to be the same—namely, the loss of sodium¹⁸² (see Lecture III.). This is entirely supported by the beneficial effects of sodium chloride in the treatment of the experimental^{13 93 128 210 271 276 310} and clinical disease.^{22 149} The sodium appears to be the controlling ion,²¹⁰ and indeed Blankenhorn and Hayman have claimed that a mixture of sodium sulphate, phosphate, and bicarbonate was as effective as sodium chloride for 17 days in maintaining the health of a patient. This requires confirmation, as remissions are common enough in Addison's disease, and sodium sulphate and phosphate are not very efficacious in sodium deficiencies of intestinal origin.

In the absence of any over-activity of the sweat glands or any obvious loss of the bodily secretions, one naturally turns to the urine in search of the channel through which the sodium is lost. Increased excretion has been demonstrated, and the simplest if not the most "intelligent"²⁴⁸ view to adopt is that in the absence of cortical hormone the renal threshold for sodium falls. Sodium salts therefore are excreted in excessive amounts even when the plasma levels are normal or subnormal. In the absence of an exaggerated intake this must inevitably lead to a sodium deficiency.

Diabetic Coma and Chronic Interstitial Nephritis

There is one other clinical cause of sodium deficiency, but I have left it to the end because it is, I think, the most difficult to understand. We know from the experiments of Haldane¹²⁴ and Dennig et al.⁶⁶ that a severe experimental acidosis induces at first a large loss of fixed base (mostly sodium), concentration of the plasma proteins, and hæmoglobin.¹¹ The acidosis must be pronounced to bring about these effects,¹⁵⁵ and even under Dennig's severe experimental conditions the loss of base did not continue for more than a few days. There was, in fact, some retention of sodium in the later stages,⁶³ and removal of the acidosis led to an immediate swing back to normal.^{66 206} The body's chief protection against such a loss of fixed base is the ability of the kidney to form and excrete ammonia.

The blood picture in diabetes and diabetic coma has been very fully studied, and is in keeping with a salt deficiency. There is no doubt for instance that in comatose patients^{135 250 262} or depancreatized animals¹⁴⁶ the plasma proteins tend to be raised and the red cells concentrated. These findings may be due solely to the water loss caused by the high blood-sugars and forced diuresis,²⁵¹ but are to be expected also

with a salt deficiency. Reverse changes take place during recovery.^{171 174} Plasma chlorides tend to move inversely with the blood-sugar in experimental and clinical diabetes of all grades of severity,^{103 220 221 234 307} and even in non-diabetic animals.⁴⁸ There may be a great reduction in the plasma chlorides in coma,^{26 27 43 87 169 249} which indicates a deficiency of extracellular electrolytes. The urinary chlorides are commonly very much diminished.^{43 87 188} It has even been suggested that the fall in serum chlorides is the cause of the insulin resistance of coma²⁵⁷ but this is not a very satisfactory hypothesis, and in any case, in spite of their absence from the urine, the plasma chlorides may be normal or even high in coma.^{8 188 251} Diabetic tissues take up the chloride ion with abnormal avidity.² A fall of serum chlorides must not be considered to be proof of a salt deficiency, and the only reliable index of this is a fall in the serum sodium. Such a fall has been demonstrated in coma and pre-coma,^{135 171 188 249} and it is natural to regard this as the result of the acidosis.^{27 239} Atchley et al.,⁹ moreover, have demonstrated by balance experiments that a loss of fixed base took place when insulin was withheld for some days from severe diabetics in whom ketosis developed. On the other hand they also observed a small negative sodium balance and a small fall in the serum sodium in another patient in the absence of ketosis, and according to Sunderman et al.³⁰⁶ there may be a rise in the total base of the serum following a single large dose of insulin to a non-ketosed subject. However that may be, the published figures for serum sodium, coupled with the knowledge that the serum volume is reduced, makes it clear that the patient in coma has lost a variable and often large fraction of his body sodium. According to Blum et al. this loss may be very considerable and amount to 40 or 50 per cent. of the total sodium in the body.^{24 28} A loss of this magnitude must mean a serious fall in the electrolytic osmotic pressure of the intracellular fluids. The total osmotic pressure may, however, be high¹⁴⁶ due to the very high blood-sugars. Assuming the concentration of sugar to be the same throughout the body fluids, the water distribution between the cells and plasma will be unaffected by the sugar, and resemble that of simple salt deficiency when the total osmotic pressure of the plasma is low. Be that as it may, the total osmotic pressure of the body will undoubtedly become subnormal under the action of insulin, and this will be accentuated if water without salt is taken with the insulin and absorbed.¹⁷¹

In diabetes the ability of the kidneys to form ammonia is normal¹⁸⁸ and only an intense acidosis will produce a serious loss of fixed base. In chronic interstitial nephritis the power to form ammonia is impaired,^{205 243 295} and in my opinion this is why a normal production of acids can bring about the loss of fixed base.²¹³ In this disease some of the general signs, which I have tried to show you are generally associated with sodium deficiency, are absent. There is no hæmo-concentration for instance. I think the explanation must lie in the secondary changes which have time to develop in such a chronic disease. You will remember that I explained the differences between the blood pictures of clinical and experimental Addison's disease in a similar way.

As is usual, however, when the serum sodium is reduced there are generally signs of dehydration and a diminished volume of the extracellular fluids.²⁵³ As in diabetic coma the total plasma osmotic pressure may not be reduced in spite of the reduction of plasma electrolytes. This is due to the very great rise of blood-urea which has usually taken place. This

urea (more certainly than glucose) is equally distributed over both cells and plasma and therefore will not affect the distribution of water between the plasma and the cells. The latter consequently are likely to be swollen up with water which they do not want and cannot get rid of, and which prevents them from functioning normally.

These then are the clinical conditions associated with a loss of extracellular electrolytes. I have attempted to give you some idea of the way in which the losses are brought about and the resulting blood changes. I have also tried to show you how these changes in turn affect the body cells. You will remember that the losses may be accompanied or followed by an acidosis, or an alkalosis—or neither, and that they are often associated with a forced loss of water. Owing to these complications and the other pathological processes which are going on at the same time, it is difficult to decide how much of the various clinical syndromes may be attributed to the electrolyte deficiency. It is indeed difficult to form a picture of the real effects of a loss of neutral sodium salts, but I shall return to this later. I propose now to discuss other aspects of these diseases and to review them in the light of the blood and tissue changes which I have already mentioned.

The Arterial Blood Pressure in Salt Deficiency

A very low blood pressure is usual in Addison's disease. It is also the rule in diabetic coma. I am not aware of any published observations on the blood pressure in the earlier stages of simple intestinal obstruction, but the later stages are accompanied by shock, collapse, and a lowered blood pressure. Claims have been made that a high salt intake may produce a high blood pressure,³¹⁶ and a low salt diet is believed by some to benefit hyperpiesis. There is then a suggestion that the lowered blood pressure of the diseases under discussion may be a reflection of the reduction of blood volume, brought about by the loss of salt or other cause of anhydræmia. I do not think this is the case, but I must defer giving you some of my reasons for saying so till my last lecture. Meantime let me remind you that in chronic interstitial nephritis, in which a low serum sodium is quite common, the blood pressure is characteristically high.

The Nitrogen Balance

There is a little clinical and experimental evidence which suggests that sodium deficiency (or dehydration) may produce a breakdown of body tissues and set up a negative nitrogen balance. The evidence is at best rather unsatisfactory, but I wish to put it before you because of its bearing on what I shall have to say subsequently. In the first place Addison's is unquestionably a wasting disease, but in the absence of accurate balance experiments one can make little of this evidence owing to the coincident nausea and anorexia. Diabetic coma is invariably accompanied by an extravagant and unbalanced nitrogen breakdown, but the uncontrolled diabetes provides an adequate explanation for it. Some of the earlier work on water deprivation is most unconvincing,^{280 299} but evidence has accumulated^{197 211} that thirst or severe dehydration from diarrhoea,²¹⁷ with or without salt deficiency,¹⁰ may produce excessive breakdown of body protein. Hartwell and Hoguet¹⁴⁰ and Haden and Orr,^{120 122 240} in their experimental work on dogs, showed that intestinal obstruction caused a much greater breakdown and excretion of nitrogen than starvation alone, and they made some confirmatory observations on patients.¹¹⁴ They showed

that the administration of saline prevented this increased nitrogen excretion, and suggested¹²² finally that it was due to a loss of chlorides, but it must be remembered that Whipple and his collaborators^{57 336 337 338} considered that the breakdown of body protein observed under similar circumstances was the result of a proteose intoxication. The two views have been reconciled to some extent by the suggestion that the "toxin" is endogenous histamine produced by the injured intestinal cells, and that its action is to accentuate the loss of chloride by its stimulation of the gastric glands.⁷ There is, therefore, uncertainty as to the cause of the tissue disintegration, and it must be admitted that experimental interference with the continuity of the alimentary canal does not provide ideal conditions for a study of the nitrogen balance, and in clinical practice it will always be negative because of the diminished intake.

SOME OBSERVATIONS ON THE EXCRETION OF ASCORBIC ACID

BY H. E. ARCHER, M.R.C.S. Eng., F.I.C., Ph.C.
 ASSISTANT CHEMICAL PATHOLOGIST TO ST. BARTHOLOMEW'S HOSPITAL; AND
 GEORGE GRAHAM, M.D. Camb., F.R.C.P. Lond.
 PHYSICIAN TO THE HOSPITAL

THE condition of scurvy in an adult is rarely seen in England. The in-patient records of St. Bartholomew's Hospital show that such a diagnosis has only been made three times in the last 22 years. The latest of these cases was diagnosed in July, 1935, when a man, aged 63 years, was brought by the police to the hospital because he had fainted in the street. The detailed investigation of this case is here recorded.

During the last two years the man had been out of work and his health had begun to fail. He was only able to walk two miles without getting tired, whereas previously he could walk eight miles. For the last six months he had tired very easily and his teeth were decaying. Four weeks previous to admission the patient noticed some difficulty in walking; his legs felt weak. For the last fortnight the appetite had been very poor. A red patch appeared on the ankles; then some pain was felt in the right knee, which swelled slightly and became discoloured with a bruise, blue at first and then red and yellow. The swelling and bruising continued to spread above and below the knee, and when he first came to the hospital, three days before admission, the legs showed petechial hæmorrhages about the ankles, and swelling and bruising of the subcutaneous tissue about the knees. It was not possible to admit him on that day, but admission was arranged for three days later. On his way to the hospital he felt very tired and sat down on a doorstep where he was found by the police in a fainting condition and brought up to the hospital.

Past health.—Gonorrhœa at 32. Right hydrocele for the last ten years. His general health had been very good and although he had travelled in many countries he had never had any tropical disease.

Condition on admission.—Well-made elderly man, looking rather ill. The eyes showed no abnormality; tongue clean. The teeth were nearly all present, but several were decayed and loose. The gums were red, soft, and much swollen, especially at the right side of the lower jaw; at this point the gum nearly reached the top of the teeth and bled easily when touched. The glands in the neck were not enlarged. The heart, lungs, and abdomen did not show any abnormal physical signs apart from the hydrocele. Blood pressure 185/70. The lower part of the right thigh was swollen and the skin was stained blue, red, and yellow. The right knee was swollen and appeared to contain a little fluid. The calves, shins, and ankles showed some petechial hæmorrhages which were almost confluent behind the ankles and heels. Œdema was present and extended half way up the calf of both legs. The tourniquet test did not cause any petechial hæmorrhages on the arms. The temperature was 98° F. on admission, and rose to 99° that night, but subsequently remained below 98·4°. The pulse varied from 60-80. Respiration 20. The urine did not contain any albumin, blood, or sugar. (Three days later a few red cells were found in the urine on microscopic examination.) The presence of swollen and bleeding gums together with bruising and petechial hæmorrhage suggested the diagnosis.

DIET PREVIOUS TO ADMISSION

The man was out of work and was living alone on a sum of only 17s. 6d. a week; he had drawn up

The remaining references of Lecture II. will appear with the concluding part of this lecture next week.

a careful budget and allowed 6s. 2d. a week for food.

Expenditure on food.		Other expenses.	
	Per week. s. d.		Per week. s. d.
Meat or fish at 4d. per day	2 4	Gas (average)	9
Egg, meat, or sardines at 2d. per day	1 2	Tobacco and matches ..	6
Bread	1 0	Washing	9
Tea, cocoa, coffee	6	Soap, stamps, &c. .. .	3
Sugar	4½	Clothes (set aside) .. .	6
Condensed milk	2½	Papers and library book	4
Butter	3	Amusements	7
Potatoes, salad, or fruit	4	Beer (Saturday night) ..	4
	6 2	Rent	6 0
			11 0

Details of diet.—Breakfast: 2 eggs or meat pie or sardines, bread and butter, coffee. Dinner: 6 oz. meat, bacon, or fish; chip potatoes, bread and butter. Supper: cocoa, bread and butter. A little salad and some stewed fruit was eaten one or two days a week. Fried onions and potatoes once a week. Green vegetables were never eaten because of the expense of the gas for cooking them. A little tinned pineapple had been eaten about four weeks before admission. It is difficult to say how much salad was eaten, but probably a very small amount as only 4d. a week was spent on potatoes, salad, and fruit. The vitamin content of the diet was thus very small.

Mr. G. T. Hankey examined the gums the day after admission and reported that the "swollen, hemorrhagic appearance of the gums is probably scorbutic."

Blood count.		Differential count.	
Hæmoglobin	54 per cent.	Polynuclear cells ..	4224 per c.mm.
Red cells	2,680,000 per c.mm.	Lymphocytes ..	1792
Colour-index	1.0	Large mononuclears ..	320
Leucocytes	6400	Eosinophils ..	40

Bleeding time, 1½ mins.; platelet count, 190,000; Wassermann reaction negative.

X ray examination of the legs did not show any subperiosteal hemorrhage.

THE DIAGNOSIS

The absence of fever and a raised pulse-rate was against the diagnosis of a septicæmia or a subacute bacterial endocarditis. The white count of 6400 and the absence of any abnormal cells excluded leukæmia and the number of platelets and the normal bleeding time a thrombocytopenia.

In order to determine the excretion of ascorbic acid, we kept the patient, who had eaten some potatoes and green vegetables for dinner, and some orange juice at tea-time on the day of admission, for the next six days on a diet containing practically no ascorbic acid; the amount excreted in the urine was estimated each day except on Saturday and Sunday.

The titration of specimens of urine for their ascorbic acid content was carried out by the Tillmans' reduction indicator 2-6 dichlorophenol indophenol modified as suggested by Harris and Ray.¹ Before titration, acetic acid was added to the dye solution in such amount that the concentration of acetic acid at the end of the titration was in the region of 10 per cent., a preliminary titration giving the clue to the amount of acetic acid required. The solution of dye was standardised against freshly prepared solutions of ascorbic acid, the check being repeated at intervals of three days. The ascorbic acid solutions were checked by titration against 0.01 N iodine. All forms of ascorbic acid administered during the tests were titrated against the dye solutions used for the urinary estimations. As far as possible fresh specimens of urine were titrated but where this was found difficult, as in the examination of the night material, the ascorbic acid that had undergone reversible oxidation was recovered by reduction with H₂S as described by Emmeric and Van Eckelen.² Grace Medes³ has shown that the pH of the urine is of great importance in this process. Experiments

in this laboratory with urines allowed to undergo partial oxidation on standing showed that if the initial pH of the urine was in the region of 6 to 6.5 treatment by H₂S resulted in a 95 per cent. recovery after the specimen had been standing for 18 hours. The results in estimating urines of very low ascorbic acid content by this method are certainly too high owing to some reduction by other constituents of the urine, but as in these investigations the substantial quantitative variations in excretion on scorbutic and ascorbic diets were of moment, the errors which must be considered in estimating very small amounts could be ignored.

The amount of ascorbic acid excreted in the urine was very small and varied from 6-18 mg. on the first six days (Fig. 1). On the seventh day 300 c.c.m.

FIG. 1.—Showing the amount of ascorbic acid excreted (diagonal shading) in relation to the amount ingested (stippling) over a period of 32 days in a scorbutic patient. When a total of 4950 mg. had been ingested the excretion amounted to an average of 53 per cent. of the intake.

of orange juice was added to the diet; the amount of ascorbic acid in this amount of juice was estimated by the dye test at 187 mg. The excretion of ascorbic acid in the next ten days was slightly larger and varied from 10 to 19 mg. a day (average 15 mg.). If it is assumed that the dye test is accurate when such small amounts are being excreted, 150 mg. were excreted out of a total of 1870 mg.—that is, a difference of 1720 mg. On the seventeenth day the dose was increased to 281 mg. which was contained in 450 c.c.m. of orange juice. On the first day of the new diet—i.e., the seventeenth day—the excretion rose to 42 mg. The ascorbic acid was not estimated during the next four days as the laboratory was closed for the August Bank Holiday and the ascorbic acid could not be preserved more than 24 hours. From the twenty-first to twenty-sixth day the excretion of ascorbic acid varied between 115 mg. and 190 mg. and the average excretion was 126 mg. a day; as the daily intake was 281 mg., 46.6 per cent. was excreted with urine. During the next five days 210 mg. of pure ascorbic acid was given each day instead of orange juice. The average excretion for the five days was 110 mg. and 51 per cent. was excreted. This shows that the pure ascorbic acid behaved in the same way as that contained in the orange juice.

THE THERAPEUTIC TEST

During the first six days after his admission to hospital the patient definitely improved in health. All the cedema subsided and the bruising of the thighs was slightly less; the fluid in the right knee-

joint disappeared. The teeth had been scaled by Mr. Hankey and the gums, touched with silver nitrate 10 per cent., showed a definite improvement, but the gums were still much swollen and bled easily. Though a little vitamin C had been given at dinner and tea on the day of admission, the improvement was probably due mainly to the rest in bed. Very rapid improvement followed the administration of the orange juice; after three days it was noted that the bruising was passing off and that the gums were retracting very quickly; after eight days there was still a little bruising round the left heel. The teeth presented a remarkable appearance; the retraction of the gums had exposed a broad band of white tooth which was in striking contrast to the stained crown. The improvement in the blood picture was also interesting:—

Date. (1935)	Hb. (per cent.)	Red cells.	C.I.
July 22nd	63	2,800,000	1.1
„ 26th	67	3,300,000	1.0
Aug. 9th	66	3,700,000	0.9
„ 21st	79	4,500,000	0.8

During this period no iron or liver was administered. The colour-index of 1.1 had raised some doubt as to the nature of the anæmia, especially as it is stated by Vaughan⁴ that the anæmia of scurvy is a hypochromic one, but Parsons and Smallwood⁵ have pointed out that even in children the anæmia may be ortho- or hypochromic in character. The rapid recovery of the patient confirmed the clinical diagnosis of scurvy.

The excretion of ascorbic acid was estimated in two other cases to see how soon the excretion of

FIG. 2.—Showing the amount of ascorbic acid excreted in relation to the amount ingested over a period of 17 days by a man on a diet deficient in ascorbic acid but with no symptoms of scurvy. No rise in the excretion occurred until 1200 mg. had been taken. The excretion rose to an average of 48 per cent. of the intake after 1600 mg. had been ingested, and to 75 per cent. after 3200 mg. had been ingested.

ascorbic acid increased and what percentage of the dose was excreted.

CASE 2.—A man was brought to hospital because he had fainted in the street. On examination he seemed ill with a temperature of 100° F. and was admitted to hospital. Although there were no symptoms of scurvy, the diet which he had been eating seemed as deficient in ascorbic acid as that of the man with scurvy (Fig. 2). The opportunity was taken to estimate the amount of ascorbic acid excreted first on an ascorbic diet, and then after a daily dose of 400 mg. of pure ascorbic acid. The amount

of ascorbic acid excreted was small (10–16 mg.) and no rise in the excretion occurred until 1200 mg. had been taken. The percentage output excreted after 1600 mg. had been eaten was 48 per cent., and after 3200 mg. 75 per cent.

CASE 3.—A healthy man who eats plenty of fruit was examined for comparison. A mixed diet was taken which contained potatoes and vegetables together with 125 c.cm. of tinned grape fruit and 70 c.cm. of tomato juice. The ascorbic acid content of this diet was 63 mg., not including that in the potatoes and vegetables. The excretion of ascorbic acid was 43 mg. and 54 mg. on the first and second day of the experiment. The diet was then changed to one containing no potatoes, vegetables, or fruit, but 400 mg. of ascorbic acid were taken each day for ten days (Fig. 3). The excretion rose to 262 mg. on the first day and to 418 mg. and 403 mg. on the second and third days. The urine was not collected on the fourth and fifth days, but on the sixth day 416 mg. were excreted. During the next four days the same diet was taken without the addition of the ascorbic acid. The excretion decreased to 92 mg. on the first day and to 23 mg. on the fourth day. The total ascorbic acid excreted on the second, third, and sixth days was 1236 mg. and the known intake was 1200 mg. This apparent discrepancy is explained by the high intake of the previous diet. It is impossible to say what percentage of the intake was excreted, but it must have been over 90 per cent.

FIG. 3.—Showing the rapid rise in the excretion of ascorbic acid in a healthy man whose previous diet had contained much fruit to whom 400 mg. of ascorbic acid was given over a period of six days. In two days the excretion had amounted to more than the known intake, showing the high previous content of the diet.

DISCUSSION

Abbasy, Harris, Ray, and Marrack⁶ have recently published some very interesting experiments on the excretion of ascorbic acid. They suggest that the estimation of ascorbic acid excreted after a single test dose is of great value in demonstrating the presence of vitamin-C subnutrition. When a healthy adult, whose habitual level of excretion was 33 mg. of ascorbic acid, was given 600 mg. he excreted 161 mg., or 27 per cent., of the dose; whereas when the level was only 14 mg., 35 mg., or 6 per cent. of the 600 mg. administered, were excreted, and when the level was 8 mg. the excretion rose only to 17 mg., that is, 3 per cent. of the amount taken in. Wood⁷ has performed this test on a woman with mild scurvy. No ascorbic acid had been detected in the urine on the day before the test and only 1.7 mg., or 0.3 per cent. of the 600 mg. ingested, was excreted in the urine. These observations after a single test dose undoubtedly show that a deficiency of ascorbic acid exists, but they do not, in our opinion, give such full information as the observation of the amount of ascorbic acid which must be given before the percentage output rises above 75 per cent. In our case of scurvy (Case 1) the significant rise in the excretion occurred when 1700 mg. had been given in comparison with 600 mg. in Johnson and Zilva's⁸ man, and with 1200 mg. in Case 2, and 1400 mg.

in Harris and Ray's case.⁹ This is a very small difference, and it would be difficult to know where to draw a line between scurvy and a potential case of scurvy, and a case of vitamin-C subnutrition. The percentage output in Johnson and Zilva's case rose to 56 per cent. after 1360 mg. and to 87 per cent. after 1480 mg. had been taken; and in Harris and Ray's case it rose to 77 per cent. after only 1480 mg. had been taken, and in our Case 2, although it reached 48 per cent. after 1600 mg. had been ingested, it did not reach 75 per cent. until 3200 mg. had been eaten. In Case 1 of our series the percentage output did not exceed 53 per cent. even after 4950 mg. had been eaten.

The observation on our single case of scurvy suggests that the percentage output is much more valuable evidence that a patient has scurvy than the amount of ascorbic acid taken before the excretion increased, or the amount excreted after a test dose.

We have to thank Miss J. Marks, M.P.S., for much assistance in the estimation of the ascorbic acid, and Miss Cambell, the sister of the ward, for her care in supervising the diet and collecting the urine.

THE TREATMENT OF
CARCINOMA OF THE CERVIX UTERI
BY THE STOCKHOLM TECHNIQUE AT THE
LONDON HOSPITAL

1929 AND 1930

BY ALAN BREWS, M.D., M.S. Lond., F.R.C.S. Eng.,
M.R.C.P. Lond., M.C.O.G.

HON. ASSISTANT OBSTETRIC AND GYNÆCOLOGICAL SURGEON
TO THE LONDON HOSPITAL

DURING the two years 1929 and 1930, 71 cases of carcinoma of the cervix uteri were referred to the obstetric and gynæcological department of the London Hospital for treatment. No case, however advanced, was refused treatment.

Four early cases were treated by Wertheim's hysterectomy (2 of these were complicated by pregnancy and the other 2 were considered exceptionally good subjects for a major surgical operation). The subsequent history of these 4 cases is as follows:—

- One died of recurrence 1 year and 5 months after operation.
- One was dying of recurrence when last seen 2 years and 8 months after operation.
- One was alive and well when last seen 1 year and 9 months after operation.
- One is alive and well more than 5 years after operation.

The remaining 67 cases were treated with radium by a technique as similar as possible to that published by Forssell and Heyman from Radiumhemmet, Stockholm. In brief, the treatment has consisted of three applications of radium, with intervals of 7 and 21 days, each application consisting of about 120 mg. of radium element, partly intra-uterine and partly

vaginal. The duration of each application has been 22–24 hours, and a heavy screenage—equivalent to 2 mm. of lead in 1929 and to 3 mm. of lead in 1930—has been employed.

For various reasons 14 of the cases did not receive the complete treatment (9 cases received two applications only and 5 cases one application only). Three of these patients died in hospital before treatment could be completed; 7 other cases were so advanced (Stage III. or IV.) and their reaction to radium was so unsatisfactory that it was deemed inadvisable to proceed with treatment; the remaining 4 were Stage II. cases and failed to come in for further treatment although advised to do so. All these 14 patients are now dead.

Until the autumn of 1930 no really effective deep X ray therapy was available for the treatment of these cases, and in this series it has been used only for the treatment of definite clinical recurrence in the pelvis arising some time after the original radium application.

DIAGNOSIS

Although some authorities are of the opinion that there is some danger of disseminating malignant cells by removing a fragment of a malignant growth for histological examination, we have felt that the advantage of confirming the macroscopic diagnosis by this means outweighs this debatable objection. In this series the diagnosis has been confirmed histologically in all 4 cases treated by Wertheim's hysterectomy, and in addition the uteri removed at operation have been preserved. In the 67 cases treated with radium the diagnosis has been confirmed histologically in 59 cases; in the remaining 8 cases in which the nature of the growth was unproved histologically, 6 have died of recurrence, 1 is untraced, and 1 only is alive and well more than five years after treatment.

RESULTS

The results of treatment with radium are set out in Table I.

TABLE I

	Cases.
Died in hospital during treatment (primary mortality 4.5 per cent.)	3
Died within first year after treatment (4 had secondary medium X ray therapy)	19
Died within second year after treatment (3 had secondary deep X ray therapy)	10
Died within third year after treatment (1 had secondary deep X ray therapy)	11
Died within fourth year after treatment (1 had secondary deep X ray therapy)	2
Died within fifth year after treatment (1 had secondary deep X ray therapy)	3
	48
Local recurrence in cervix 4½ years after treatment. Still alive after recent fourth application of radium.	1
Recurrence in bladder 19 months after treatment. Now alive and well 4½ years after fourth application of radium to recurrence	1
Recurrence in bladder 14 months after treatment. Now alive and well 5½ years after fourth application of radium to recurrence	1
Alive and well with no clinical evidence of any recurrence more than 5 years after treatment (1 had secondary deep X ray therapy)	15
Untraced	1
	67

It will be seen that there are 16 five-year cures out of 67 cases treated with radium—that is, 24 per cent.

The 59 cases treated with radium and proved histologically to be carcinoma consisted of 54 in which the carcinoma was epidermoid in structure and 5 in which it was of glandular columnar-celled type. In the former group 14 are alive and well after more than 5 years, and in the latter 1 patient is alive and well after a similar period.

In Table II. these 67 cases treated with radium are grouped into the four stages according to the anatomical extent of the growth recommended by the Radiological Sub-Commission of the League of Nations, Geneva, 1929.¹ The following results are shown:—

TABLE II

Stage	I.	..	15 cases with 6 five-year cures	..	Per cent.
"	II.	..	20 " " 6 " " "	..	40
"	III.	..	25 " " 4 " " "	..	30
"	IV.	..	7 " " 0 " " "	..	16.6
					—

Stages I. and II. constitute cases probably operable, and if the results are combined then there are 35 cases with 12 five-year cures—34.3 per cent. When Stages III. and IV., which constitute the cases probably inoperable, are combined then there are 32 cases with 4 five-year cures—12.5 per cent.

Table III. represents an analysis of the effect of age-incidence of the disease on the results obtained with radium treatment in this series of cases.

TABLE III

Age.	Cases.	Five-year cures.
20-29 2 0
30-39 7 3
40-49 25 3
50-59 19 6
60-69 9 3
70-79 5 1

The high primary mortality of 4.5 per cent. is due to 3 deaths occurring during treatment in hospital.

CASE 21.—This patient had a Stage II. carcinoma of the cervix, which was treated with one Stockholm application of radium. Under the same anaesthetic a primary carcinoma of the left breast was treated by the insertion of surgical radium needles. The patient died one hour after her return to the ward, and a post-mortem revealed that the cause of death was hæmopericardium secondary to perforation of the heart by a radium needle inserted under the left breast penetrating an intercostal space. If this case is excluded—and the death cannot reasonably be attributed to the Stockholm treatment of carcinoma of the cervix—then the primary mortality is 2 cases out of 67, that is, 3 per cent.

CASE 31.—A patient, aged 70, with Stage II. growth, died eight days after the second application of radium with spreading peritonitis. Post-mortem examination revealed gangrene and infection of the left half of the fundus of the uterus. The growth was scirrhous, constricting the cervical canal, and associated with pyometra. Had the pyometra been drained for a week or ten days prior to radium treatment, then in all probability this death would not have occurred.

CASE 53.—A patient, aged 22, with a Stage IV. growth, had a marked febrile reaction and recurrent secondary hæmorrhages following the first application of radium. She remained in hospital for twelve weeks and died ten days after the second application of radium. This death can be more fairly attributed to the final stages of the disease than to its treatment with radium.

TABLE IV

Year.	Number of cases.	Percentage of five-year cures.
1920 96 27.1
1921 115 23.5
1922 130 20.0
1923 105 23.8
1924 149 23.5
1925 134 14.2
1926 143 25.9
1927 143 25.9
1928 128 23.4
1929 152 30.3

An abstract of the results of treatment of carcinoma of the cervix uteri with radium at Radium-

hemmet, Stockholm, for the years 1920 to 1929,² is given in Table IV.

If these ten years 1920-29 are combined, then 1295 cases of carcinoma of the cervix were treated at Radiumhemmet with 308 five-year cures. This gives an average five-year cure per year of 23.8 per cent.

The treatment of the cases described above has been entirely carried out in the obstetric and gynaecological department at the London Hospital by Mr. Eardley Holland, Mr. Victor Lack, and myself. I am immensely indebted to my senior colleagues for allowing me to organise the treatment, and for allowing me to follow up and publish their cases. It is only their consistent adherence to our agreed technique that has made it possible for us to establish the value of this treatment in a consecutive series of cases. I am also indebted to the Yarrow research fund of the London Hospital for financial help in the initial years of organisation.

The secondary, medium, and deep X ray therapy, when employed, was entirely prescribed and supervised by Dr. G. E. Vilvandré and Dr. M. H. Jupe, the honorary radiologists to the hospital.

DISEASES OF THE CHEST, QUEEN MARY'S HOSPITAL,
AND THE ROYAL WATERLOO HOSPITAL

THE increasing use and popularity of upper partial thoracoplasty in the treatment of tuberculous cavities in the lung has led to the development of this operation as a specialised procedure aiming at permanent collapse of these excavated areas, yet still leaving the base and greater part of the lung as a functioning organ. In a previous paper we have outlined the principles which govern the selection for surgical treatment.

In the case of an apical thoracoplasty the operation has usually been an exaggerated form of the upper stage of the standard Sauerbruch paravertebral operation involving resection of considerable lengths of the upper four or five ribs under which the diseased area lies. Pulmonary collapse is obtained by a threefold movement of the divided ribs. The posterior cut ends of these anterior portions fall inwards and downwards so that the end of the first rib may lie in close proximity to the second and third transverse process. A certain amount of lateral collapse is also obtained by the downward swing of the main curve of the ribs—the so-called "bucket-handle" action—but in the upper chest this effect is not nearly so noticeable as in the lower part. Whereas the posterior part of the lung apex is set free, the remainder is held attached to the deep aspect of the first rib and, as may be judged from X ray films, undergoes only a small descent. The main part of the collapse is effected in the transverse rather than in the vertical axis.

This form of thoracoplasty not infrequently fails when the cavity is centrally placed or is lying close to the mediastinum. The cavity admittedly becomes reduced considerably in size, but may persist in part as a pear-shaped slit with the long axis vertically placed. The lesion then still remains as an open source of infection and the only remedy for this state of affairs is the performance of an anterior and/or lateral supplementary rib resection. (Figs. 1 and 2.) The amount of scarring produced by the original operation precludes the successful practice of any form of extrapleural pneumolysis as a subsidiary procedure.

It has been common practice in certain hands to facilitate the amount of collapse obtained by an apical thoracoplasty by means of extrapleural stripping. Semb and Holst in a large number of cases have carried this dissection posteriorly into the paravertebral gutter removing the heads of ribs and upwards over the lung dome allowing fascia and muscular bundles to add their weight to the collapsing lung. Radiologically this collapse obtained by this "extrafascial apicolysis" is definitely superior to that produced by the standard operation, but the vertical fall of the apex does not always ensure collapse of cavities close to the mediastinum.

Our experiences with extrapleural pneumolysis and extensive stripping of the parietal pleura from the ribs carried out from in front preparatory to filling the cavity with paraffin wax have led us to

believe that the danger of stripping the pleura from the mediastinum is negligible—a fear that has presumably hindered the common practice of this form of mobilisation over a large area. It was consequently decided to perform the stripping over the whole

FIG. 1.—Big right apical cavity. Small pneumothorax space towards apex. Right diaphragm raised.

FIG. 2.—After posterior thoracoplasty of upper five or six ribs followed by anterior thoracoplasty Ribs 2 to 4. The cavity though greatly diminished can still be seen below the clavicle at the level of the fourth to fifth vertebrae. This illustrates the persistence of a cavern in spite of extensive rib-resection.

diseased area of the apex in addition to performing the ordinary form of extensive removal of the upper ribs. Gravesen has given the name "cupolaplasty" to this form of operation. A necessary factor in performing this type of operation, as with any form of extrapleural pneumolysis, is fusion of the pleural membranes over the area to be collapsed. This is more commonly found than might be expected, for most of the cases are of long standing and pneumothorax treatment has previously been tried and failed,

FIG. 3.—Right localised upper zone disease showing fibrosis and cavity formation.

FIG. 4.—After complete apicolysis and resection of Ribs 1 to 4 fluid level is seen and is extrapleural with dense zone of compressed lung tissue between it and the diaphragm.

FIG. 5.—Three weeks later fluid was absorbed and lung has re-expanded, but not above the level of the fourth to fifth transverse processes.

or tried and abandoned. The pneumothorax has usually been abandoned on account of the presence of adhesions over the diseased apical area. Even in cases in which we might have had some doubt as to whether the pleural cavity was completely adherent over the operation field there has been no untoward

removal of a further length of the anterior part of the third rib is carried out, it being recalled that a section of this rib had been removed preparatory to stripping. Then according to the amount of collapse required part of the fourth and/or fifth ribs are resected. We have made it customary to grade the collapse and prevent a sharp shelf being left by removing a short piece of bone in the rib or two below the major part of the resection.

The operation is completed by suture of the muscles and skin after hæmostasis has been assured. Originally we omitted drainage of the wound in the hope that the blood-stained serum that was bound to collect would act as a pad in the dead space and would help to maintain the collapse, until such time as the soft tissues had time to fall in and obliterate this space. The risk of infection, however, is considerable and in consequence we prefer to drain the wound for several days.

There is certainly some tendency for the stripped apex to re-expand unless the rib-resection has been extensive, and to overcome this we have, in a few cases, divided the intercostal periosteal-muscular bundles either anteriorly or posteriorly and sutured them to each other and to the inner aspect of the thoracic cage at a lower level so as to form a grid or coarse meshwork close over the depressed apex. As periosteal regeneration occurs, this forms a rigid barrier beyond which the lung cannot re-expand.

RESULTS

The amount of shock produced in an operation of this character is very little greater than that produced by a rib-resection of the same magnitude; in no case have we found it necessary to perform an operation involving five or six ribs in two stages. As against this it must be admitted that the convalescence is rather more disturbed over the first few days—the temperature and pulse are raised and if a big cavity is present there is usually abundant sputum about the third to eighth day, but pain is not conspicuous, nor is the deformity any more noticeable than with a simple thoracoplasty. The risk of infection of the dead space in this type of patient has been noted, but such infection occurred only in cases that were not drained, and did not lead to serious ill-effect.

X ray films taken shortly after the operation show a collection of fluid lying over the lung apex which is often depressed almost to the level of the hilum. This fluid certainly adds to the collapse actually produced by the stripping, but as time goes on the fluid is absorbed and the upper limit of the lung edge rises to a small extent before becoming stationary. In dealing with firm-walled apical cavities there is no doubt that the operation produces a radiological collapse far superior to that obtained by any other procedure that we have employed with the possible exception of extrapleural pneumolysis with wax implantation. But this latter is accompanied by the

FIG. 6.—Big infraclavicular cavity on the left.

FIG. 7.—Film taken ten days after operation showing depression of the apex of the lung below the fourth vertebra and almost complete obliteration of the cavity. Complete closure obtained later.

circumstance such as might be occasioned by tearing of the parietal pleura.

TECHNIQUE

The operation commences as an ordinary upper thoracoplasty, and the muscles attached to the vertebral border of the scapula are divided through a J-shaped incision made midway between the scapula and spinal column. The scapula is lifted off the chest wall and the upper ribs are exposed. The periosteum of the third and possibly the second ribs is removed and an extensive length of both bones removed. Before proceeding to do anything to the first rib this stripping is done, and it immediately renders the subsequent removal of a long length of the first rib considerably easier. To effect the stripping the finger is carefully worked into the rib-bed until the space normally occupied by the endothoracic fascia is found. The plane of separation is easily recognised and dissection is carried upwards and outwards with the fingers within the rib framework until the whole of the apex is freed. Steady and careful pressure enables this stripping to be done without difficulty, though occasional resistance is encountered in the form of firm bands of adhesions. These, however, can be overcome safely so long as the finger pressure is kept well to the deep surface of the ribs. When the apex is free it falls downwards to a marked degree and if further depression is required it can be carried out beyond the lower limits of the third rib. There is slight oozing from the raw bed, but this stops readily and the apex can be held down with a swab while the remaining part of the rib-resection is performed. These ribs are now freed of their periosteum preparatory to their resection, and one of the chief advantages of the preliminary stripping lies in the fact that the deep surfaces and even the anterior parts of the upper two ribs can be easily reached. It is possible to remove the whole of the upper two ribs without encountering any of the difficulties that occur in other forms of this operation. At times

not infrequent complication of extrusion of the wax at a very variable period after the operation.

The following cases illustrate the results obtained with the combined pneumolysis and thoracoplasty:—

1. Woman aged 23. Chronic left apical disease with cavity known to be present three years. A.P. (artificial pneumothorax) failure. Complete apical stripping with resection of upper four ribs. Total length of rib removed, 22 in. Cavity obliterated rapidly. Patient started to put on weight a fortnight after operation. No. T.B. (tubercle bacilli) in sputum.

2. Man aged 26. Extensive right upper zone cavitation. A.P. failure. Complete apical stripping with resection of upper five ribs. Total length of rib removed, 21 in. Good apical collapse was obtained.

3. Woman aged 20. Right apical fibrocavernous disease. A.P. failure. T.B.+. Complete mobilisation of apex with resection of ribs, 1, 2, 3, and part of 4. Total length, 16 in. Wound not drained. Thin seropurulent fluid collected in the dead space and discharged through the wound on the twelfth day. The sinus ultimately closed. Patient has put on over 2 st. in weight. T.B. absent. (Figs. 3-5.)

4. Man aged 31. Right apical cavities. T.B.++. A.P. failure. Complete apical stripping and resection of ribs 1, 2, 3, 4, and part of 5. Total length, 18½ in. A "grid" of muscle and periosteum. Wound not drained. Collection of fluid in dead space compressed lung and about three weeks after operation broke through into a bronchus. Blood-stained fluid was coughed up for several days and the extrapleural cavity emptied. Ultimate result good. T.B. absent.

5. Man aged 34. Large single cavity of left apex. T.B.+. Complete apical stripping and resection of ribs 1, 2, 3, 4, and 5. Total length 26 in. A "grid" was made over the apex. Successful collapse. Highest point of lung lies between the levels of the fourth to fifth transverse processes. (Figs. 6 and 7.)

As regards the end-results it is too soon to judge. The operation, however, has as its primary aim closure of cavities and in this it would appear to be more satisfactory in selected cases of localised apical disease than any method that we have previously employed.

STENOSING TENDOVAGINITIS AT THE RADIAL STYLOID PROCESS

BY B. H. BURNS, B.Chir. Camb., F.R.C.S. Eng.
ORTHOPÆDIC SURGEON TO ST. GEORGE'S HOSPITAL; AND

V. H. ELLIS, B.Chir. Camb., F.R.C.S. Eng.
ORTHOPÆDIC SURGEON TO ST. MARY'S HOSPITAL;
ASSISTANT SURGEON, ROYAL NATIONAL ORTHOPÆDIC
HOSPITAL

STENOSING tendovaginitis was first described by de Quervain¹ in 1895, and subsequently by Hoffmann² in 1898. Since that time nearly 200 cases have been reported, mostly by continental writers. We are aware of only one case recorded in this country³; yet the condition is by no means uncommon, and it is perhaps almost the only cause, in our experience, of pain in the region of the styloid process of the radius with disability in movements of the thumb. Stenosing tendovaginitis occurs far more often in women, but among our 28 cases there were 3 men. In this series the ages range from 15 to 49, the commonest age being about 35. There was usually a history of some two to four months' pain, coming on insidiously without definite history of trauma. The majority of the women were engaged in household work, and the commonest complaints were of

pain on wringing and a tendency to drop things, particularly in movements involving radial abduction, as in lifting a kettle. The condition sometimes occurs in an acute form in turnip toppers, but this occupation being seasonal it seldom becomes chronic in these patients.

The symptoms and signs are typical. Strong active abduction of the thumb is painful. There is a visible swelling over the styloid process of the radius (Fig. 1), which in some cases may partially obliterate the anatomical snuffbox. It extends for a short distance up the radius, and there is tenderness over the swelling.

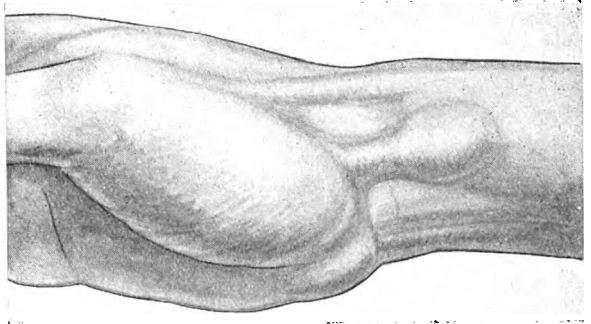

FIG. 1.—Drawing showing a particularly well-marked swelling; more commonly the swelling is less definite.

The diagnosis is certain if, on grasping the patient's thumb and quickly adducting it, there is sharp pain over the styloid process. The condition is due to obstruction of the free movements of the tendons of the extensor ossis metacarpi pollicis and extensor brevis pollicis as they pass beneath the dorsal carpal ligament.

Morbid Anatomy.—The fibrous tendon sheath of the two tendons is thickened, and in severe cases may be as much as four times the normal thickness, which is 1/32 in.⁴ The lumen of the sheath is narrowed. In mild cases the slight thickening of the tendon sheath may be the only finding, but in the more severe cases the narrowing of the lumen produces a constriction and even flattening of the tendons, which may be bulbous beyond the constricted area. The thickened sheath may have lost its lustre and be brownish in colour; new blood-vessels may be observed in it. It may have an almost cartilaginous consistency, and frequently appears hyaline or oedematous. Occasionally there is a synovial effusion, but the synovial membrane is not thickened and may be absent, with consequent adhesions to the tendon. These adhesions, composed of new fibrous tissue, appear almost like a pannus, and are not readily stripped from the tendon.

A section of the thickened sheath shows large quantities of new fibrous tissue, which is markedly cellular. A few new blood-vessels may be observed surrounded by lymphocytes and an occasional plasma cell. In the more superficial layers, which appear to be those of the original sheath, elastic fibrils are present. Some of the fibrous tissue shows mucoid degeneration.

Differential Diagnosis.—The only other conditions likely to be confused with this one are fractures of the scaphoid, in which there is tenderness in the anatomical snuffbox with weakness of the wrist. But in these cases there is no tumour, and the diagnosis is confirmed by radiography. The more difficult differential diagnosis is from sprain of the external

lateral ligament of the wrist, which is a much less common condition. Careful examination will show that the tenderness is limited to an area distal to the radial styloid process, and whereas adduction of the whole hand is painful, that of the thumb alone is not so.

Treatment.—Cases have been reported where fixation of the thumb in abduction has relieved the

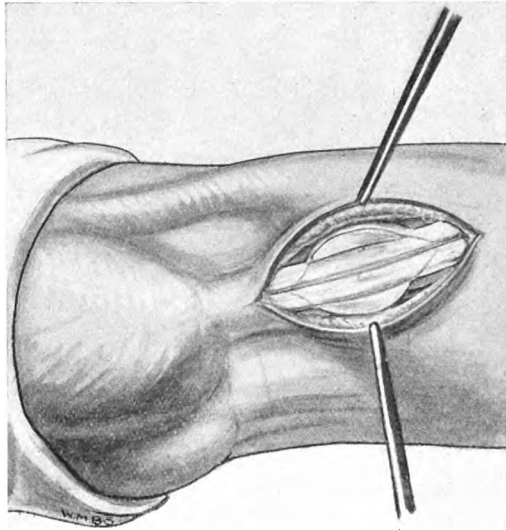

FIG. 2.—The short extensor tendons are exposed and the superficial part of the thickened sheath cut away showing this structure in section.

symptoms (Hoffmann), but in three of our earlier cases this method was unsuccessful. de Quervain first treated these cases by simple incision of the constricting sheath. This manœuvre produces immediate relief, and in no cases has it failed. It is therefore obviously the method of choice. Local anaesthesia is satisfactory. An incision is made through the skin over the swelling and the fibrous sheath partially excised (Fig. 2). The free motion of the tendons is immediately obvious, and only the skin need be sutured.

We have not considered it necessary to report our 28 cases in detail, as they are essentially similar and the results of operation are uniformly satisfactory. They may be summarised as follows:—

Analysis of 28 Personal Cases. (16 V. H. E. 12 B. H. B.)

3 males, 25 females, ages 15–49 (Mode. 35).

22 treated by operation. All cured immediately.

3 treated by plaster, with no permanent relief.

3 refused treatment. One of these went to another hospital, where manipulation was performed with no benefit.

With others, we have been struck by the similarity of this condition to the thickening of the tendon sheath which causes snap fingers and thumb. Similar thickenings have been found in other tendons about the wrist—namely, the extensor carpi radialis longior, the extensor carpi ulnaris, and the flexor carpi ulnaris.

A CASE OF PEMPHIGUS ACUTUS

BY FRANK L. KER, B.A. Camb., M.B. Edin.

SENIOR ASSISTANT, LITTLE BROMWICH HOSPITAL,
BIRMINGHAM

THE following brief record of a case of pemphigus acutus (butcher's pemphigus) may be of interest on account of the rarity of the condition.

History.—The patient, a man of 21, commenced work as a slaughterman five weeks before admission to the Little Bromwich Hospital on Nov. 3rd. From Oct. 17th to 26th he had been treated for a septic finger—the result of a prick at work. On the day before admission he noticed some small red papules on his chin, which spread rapidly during the ensuing 24 hours, involving his cheeks and both upper limbs, many becoming vesiculated. His general health was good, but he reported to his doctor and was notified as a case of suspected glanders. The patient, who had lived in the country all his life, had never been vaccinated. Subsequent inquiries at the slaughter-house revealed that no animal had been slaughtered recently which was suffering from any unusual disease.

Examination on admission showed a well-developed youth whose face and upper limbs were the site of vesicular and pustular lesions, varying in shape and size, the largest being about an inch and a half in the greatest diameter. The majority were round, while some were oval and others irregular. All were surrounded by an area of inflammation. A few were umbilicated and others were discharging a seropurulent fluid. The lesions on the face were mainly confined to the chin and cheeks, the forehead being almost unaffected. The trunk was clear, but the extensor aspects of the thighs showed a few papules with some small vesicles. There was a small healing scar with a central scab over the first interphalangeal joint of the ring finger of the left hand. The tongue was heavily furred, while the throat was very congested and both tonsils were covered with a thin film of exudate. The breath was fetid. Temperature 101° F.; pulse-rate 124; respirations 24. No evidence of a primary chancre could be found and the Wassermann reaction was negative. Fluid aspirated from the lesions gave no *Bacillus mallei* or *Streptothrix actinomyces*, but a good growth of non-haemolytic streptococci was obtained.

Progress.—Lesions continued to appear for five days after admission, the scalp and back becoming involved, while the anterior aspect of the trunk remained clear. The throat was exceedingly painful and as a result swallowing was almost impossible, but no vesicles appeared on the throat or palate. The temperature remained elevated until the rash was fully developed, reaching a maximum of 103° F. on the evening after admission. The condition gradually subsided and except for a rise in temperature ten days after vaccination—which was performed on Nov. 4th and produced local pain and inflammation—convalescence was uneventful. The lesions slowly crusted and when these separated no scar was left. The patient was dressed three weeks after admission to hospital and discharged a week later. He reported a month after discharge when all that could be seen was slight bluish staining of the skin where the lesions had been. His general health was excellent.

Treatment.—The larger blisters were removed with scissors, leaving raw deeply congested areas, many showing a clear central vesicle. New vesicles were punctured as they appeared. Further treatment was directed to relieve the intense discomfort caused by involvement of so large an area of the body. A bland ointment consisting of three parts of lanoline and one part of olive oil with ½ per cent. carbolic acid was found beneficial when applied spread on thin muslin. Antistreptococcal serum (20 c.cm.) was given intramuscularly on the third day. When the temperature had settled he was given permanganate baths.

All the nursing staff while attending to him wore gowns, rubber gloves, masks, and goggles, and their arduous task was made very unpleasant by the putrefactive

odour which pervaded the room. His recovery is due to their untiring energy on his behalf.

The case is of interest for several reasons, namely: (1) The similarity of distribution to that of the lesions of small-pox and the rapidity with which they went through the same stages as the small-pox lesion. (2) The absence of any prodromal symptoms. (3) The slightness of the general disturbance considering what large areas of the body were involved. (4) The isolation

of non-hæmolytic streptococci from the lesions, which are usually attributed to the diplococcus of Pernet and Bulloch. (5) The rapid recovery from a condition which in its severe forms is usually fatal.

I am indebted to Dr. J. McGarrity, medical superintendent of the hospital, for permission to publish this case; also to Dr. H. G. M. Henry, of the City Laboratories, for the bacteriological reports.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF MEDICINE

At a meeting of this section held on March 24th the chair was taken by Sir CHARLTON BRISCOE, the president, and Sir WALTER LANGDON-BROWN opened a discussion on the

Medical Aspects of the Menopause

No one, he said, could doubt the importance or the complexity of the subject. The special endocrine difficulties of the menopause could be referred to two causes: (1) the fact that woman, unlike other mammals, had no phase of anestrus; and (2) the bisexual activity of the ovary. Woman started at the menopause a running-down of a clock which had never, since puberty, stopped going; the uterine endometrium knew no rest. The interdependence of pituitary and ovary was now recognised; the anterior lobe liberated œstrin. The study of basophilism had led to interesting physiological deductions. The basophils were inhibitors and the eosinophils were stimulators of the ductless glands. The medulla of the ovary had been described as male and the cortex as female. This bisexuality must greatly increase the upset of the organism when the female part ceased to function. The endocrine state before the menopause had a considerable influence on the abnormal conditions produced by this change. The stout, lethargic arthritic woman apt to have headaches would benefit by thyroid at the menopause; the thin excitable type would not. The obesity of the climacteric seemed to be of the pituitary type, but some women at this time took on an acromegalic appearance. It appeared that when the ovary began to fail the pituitary made a temporary effort to compensate by producing increased sex hormone, and this completely upset the balance. For this reason symptoms could often be relieved—though only temporarily—by giving œstrin. The adrenals also showed increased activity, and the thyroid was speeded up in the direction in which it was already tending.

The vascular changes did not include any intrinsic cardiac changes but there was temporary or permanent hypertension and vasomotor instability. The former might depend on basophilic pituitary activity; these cells often showed hyaline change. The instability seemed to be a direct result of lack of œstrin and the adrenals played a considerable part in its production. Blood pressure rose during shivering and fell steeply during the subsequent flushing. Œstrin preparations alleviated these symptoms, but in some cases they appeared years after oöphorectomy; possibly an undefined cellular change accounted for them. The diencephalon was now regarded as the head ganglion of the sympathetic nervous system and the centre for many emotional phenomena. It also influenced gastric motility. The pituitary was the intermediary between the diencephalon and the gonads.

Purely psychical factors must also be considered and the attitude with which a woman approached the change was of great importance. Women must not feel that their usefulness was ended but must make investments of interests to continue after the menopause. The hypothyroid type tended to suffer from the fibrocytic form of arthritis. The human corpus luteum did not produce a hormone to relax the pelvic ligaments at parturition—another penalty women had to pay for the upright position. Multiparæ often had a recurrence of backache at the menopause. Diathermy to the cervix was sometimes useful in this trouble, restoring some function to the ovary. But endocrine disturbances in most cases did no more than provide a suitable soil for joint disturbances. Treatment of the menopause was mainly symptomatic: iodine, liquor sedans, and small doses of thyroid were useful in suitable cases. Vasomotor symptoms were relieved by œstrin. Suggestion was a factor in the use of modern endocrine preparations. Menopausal women usually had an excess in the blood of the hormone found in the urine of pregnant women and this preparation was not, therefore, of any use. Valerian had a real sedative influence on the autonomic nervous system. The psychological part of the treatment must never be forgotten; often a time of retreat was desirable while the endocrine system settled down to a new and more stable equilibrium.

Dr. A. P. THOMSON analysed the cases coming to him as a general physician. The neglect of the subject in text-books was surprising. The best review of the subject was that published by the Medical Women's Federation in 1933. This had shown that 15 per cent. of women had no symptoms, while 10 per cent. were definitely disabled. The most numerous intermediate group presented the symptoms of an ordinary anxiety neurosis: the fear that their attraction and value would disappear and the fear of cancer. Among the poor the menopause was often welcomed. In a large group the symptoms of thyrotoxicosis threatened and came to nothing; radical treatment should be advised only with very great caution. Permanent thyroid changes dated from the menopause in rather less than 2 per cent. of the women reviewed by the Medical Women's Federation. The results of psycho-analysis in Dr. Thomson's cases had been bad. Women were frequently referred to him on the threshold of some gynæcological intervention to see if the heart would stand it. The murmur was usually due to simple anæmia and the patients were quite well in a month or two, their hæmorrhage and other menopausal symptoms having disappeared with rest and tonic treatment. He suggested that no woman should be submitted to operation until simple medical measures had been tried. Some doctors had an odd faith in insulin for uterine hæmorrhage; if insulin really inactivated œstrin diabetics would have menorrhagia instead of the usual amenorrhœa! A simple and

valuable treatment was bleeding, which had been widely used in the sixteenth century, and certainly relieved flushing, especially if there was hyperpiesis. The most important late symptom was obesity; it occurred twice as often in married women as in single ones. This seemed to relate to their greater ability to take care of themselves, whereas the single woman had to carry on. An arthritis of the knees might occur in women at the menopause who became fat, owing to wear and tear; but Dr. Thomson had never seen a case in a thin woman. The psychotic group represented the physician's failures. Quite a large number of alcohol and drug addictions began at the menopause.

THE PITUITARY AND OVARIAN RELATIONSHIP

Dr. P. M. F. BISHOP said that the gradual decline of ovarian activity was undoubtedly the starting-point, and a compensatory over-secretion of prolan A followed. It seemed logical to treat with œstrin, and this had met with some success. The symptoms, however, were not due to withdrawal of œstrin but to the presence of prolan A; they did not appear until four or six weeks after oöphorectomy. The prolan A curve ran more or less parallel with the hot flushes. Estrin damped down the prolan A production. When both prolan A and œstrin were absent from the urine, hot flushes never appeared. Propylactic treatment seemed highly undesirable. The object of œstrin administration was not to cut out prolan A altogether but to keep it down and let the patient become gradually accustomed to higher and higher levels of it. There was usually no need for high doses or injections, or of œstrin estimations. Doses of 500-1000 international units were generally sufficient; and the flushes themselves were a good enough indication of the imbalance. Patients often said they felt well during œstrin treatment; and a valuable change of mental attitude was sometimes effected thereby.

Dr. F. STOLKIND thought reassurance was very valuable treatment. Endocrine preparations by mouth were waste of time and money and the results from injections were probably psychological. He had not seen any benefit from diathermy to the cervix, bleeding, or psycho-analysis.

Dr. A. H. DOUTHWAITE agreed that menopausal arthritis of the knees was simply an osteo-arthritis related to the increased weight, but questioned whether there were not also a true rheumatoid arthritis related to the menopause, less crippling than in younger people and very resistant to treatment. Complete achyria often suggested chronic gastritis in these cases and the blood uric acid was above normal, though lowering it did not relieve the symptoms. Venesection did relieve symptoms if hyperpiesia was present.

Dr. PHILIP ELLMAN mentioned a syndrome of obesity, arthritis, and hypertension in women with definite hypothyroidism. The disturbance of equilibrium due to excessive fat produced the joint changes. Astonishing results were obtained by thyroid medication, especially relief of the arthritic symptoms. Menopausal acromegaly was another syndrome, and in one case had been repeatedly relieved by intrapelvic diathermy—possibly for psychological reasons. The syndrome of obesity, hypertension, and hypothyroidism was not an uncommon late sequel of artificial menopause with removal of the ovaries.

Sir WALTER LANGDON-BROWN, in reply, agreed that many women looked forward to the menopause as a chance of pursuing their intellectual interests

without interference. Cancerophobia was one of the commonest diseases of the day. The high percentage of achlorhydria was probably a factor of increasing age. Psychological treatment was of the greatest importance but formal psycho-analysis was likely to do more harm than good.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

A MEETING of this society was held in Sheffield on Feb. 28th, with Dr. RUTH NICHOLSON, the president, in the chair. A joint communication on

Radium Treatment of Carcinoma of the Cervix

was made by Prof. W. FLETCHER SHAW and Prof. DANIEL DOUGAL. They had been struck by the fact that although radium treatment of carcinoma of the cervix had been practised in this country for many years, there had been singularly few reports based on five years' freedom from recurrence. The staffs of institutions where radium treatment was carried out had stated that they were obtaining good results but had not as yet published any figures comparable with those from foreign clinics. On the other hand, the results likely to be obtained by the Wertheim operation were well known. Unfortunately this operation entailed both a high immediate mortality and a long and trying convalescence, and for this reason most gynæcologists would undoubtedly have been prepared to abandon it if convincing evidence had been produced by the radiologists that radium treatment could give equally good results. Such evidence had not as yet been forthcoming in this country and for this reason Prof. Shaw and Prof. Dougal had determined in 1928 to purchase their own supply of radium and to treat their own cases both in private and in hospital. As this step was in the nature of an experiment, it was decided to treat all cases by the same method and to follow up every case with the idea of publishing results as soon as a sufficient number had been collected.

After due consideration the method of Heyman of Stockholm had been chosen, with certain modifications suggested by Dr. Helen Chambers and Prof. S. Russ of the Middlesex Hospital. Forty milligrammes of radium, suitably screened, was inserted into the uterine cavity and 60 mg. in three box applicators was applied to the cervix and vaginal fornices. Each patient was treated on three occasions for 24 hours, with an interval of one week between the first and second application and three weeks between the second and third application. The cases treated up to Jan. 1st, 1931, numbered 94, and the results five years later were:

Alive and well five years later	39 (41.4%)
Dead or untraced	55 (58.6%)

The immediate mortality was 2.1 per cent., one patient having died from peritonitis and one from pulmonary embolism. Microscopical confirmation had at first not been carried out in advanced cases, because the diagnosis in such cases was deemed to be so definite to an experienced clinician that confirmation was unnecessary. Later, when it was realised that readers of the report would not have seen the cases, and would have to accept the diagnosis on the authors' unconfirmed statement, a piece of growth was excised for laboratory examination as a routine. Microscopical examination was therefore carried out in about half the cases; but those not so examined were so advanced that no error in diagnosis was possible.

In considering the results with regard to the stage of the growth, the classification of the radiological subcommittee of the League of Nations Cancer Committee had been adopted.

Stage.	Cases.	Alive.	Dead.
I.	11	7	4
II.	27	12	15
III.	40	17	23
IV.	10	1	9

Six cases were unclassified.

Two patients with cervical stump carcinoma following subtotal hysterectomy were included, and both died of recurrence. These cases should perhaps have been omitted, for it had obviously not been possible to follow the full routine as regards application.

In considering the question of radium versus the Wertheim operation, the results in the present series (94 cases with 41.4 per cent. of five-year cures) could be compared with the surgical results of Bonney (384 cases with 39 per cent. five-year cures) and Fletcher Shaw (154 cases with 38.3 per cent. five-year cures). The operability rate had also to be taken into consideration (Bonney 63 per cent.). Prof. Shaw and Prof. Dougal considered their series a small one; whether the high percentage of freedom from recurrence would be maintained when they had larger figures remained to be seen. But they were convinced that the results with radium were better than those with Wertheim's hysterectomy. At the same time they were by no means satisfied with figures which showed less than half the patients alive after five years. Certain of their patients were now having deep X ray therapy after radium treatment, but this had been done for too short a time to allow of any comparison of results. They were convinced that the surgical treatment of carcinoma of the cervix was a thing of the past.

The PRESIDENT congratulated Prof. Shaw and Prof. Dougal on the excellence of their results. She read on behalf of Mr. P. Malpas the figures from the Liverpool Radium Centre, of cases treated during the years 1929 and 1930, the total five-year survival-rate of all cases treated being 33 per cent. The method used was that of Heyman, followed by deep X rays.

Mr. J. W. BURNS asked if any of the patients had suffered from annular constriction of the rectum after treatment. He had observed the condition in 2 cases. He also expressed the view that radium therapy was well worth while even in very advanced cases, since it relieved pain and made the end easier.

Mr. T. F. TODD commented on the excellence of the results obtained, which he regarded as far and away ahead of anything else so far achieved. Except for one single year's results from the Marie Curie Hospital, he knew of nothing comparable in the international literature. He considered radiation definitely preferable to surgery even in early cases; at least eight of the international radium centres had published a five-year survival-rate of over 50 per cent. in operable cases—i.e., 10 or more per cent. better than surgery. Mr. Todd recalled Beckwith Whitehouse's published figures of 500 cases treated at several teaching hospitals in this country, with a five-year survival-rate of about 11 per cent.

Dr. FRANK ELLIS gave figures from the Jessop Hospital for Women, Sheffield, showing a 30 per cent. five-year survival-rate. It was customary in Sheffield to perform Wertheim's operation on Stage I. cases (if fit for operation) after preliminary radiation. If the tumour was bulky and infected the patient had (1) X ray treatment for two weeks to the whole pelvis; (2) two weeks' rest with douches; (3) radium; (4) one day later, Wertheim's operation; and

(5) further X ray treatment to the whole pelvis if glands were found to be involved. If the tumour was small and uninfected, the procedure was: (1) single dose of radium; (2) one day later, Wertheim's operation; and (3) a full course of X rays to the whole pelvis if glands were involved. Cases in Stages II., III., and IV. were given X rays, radium, and then X rays again. Dr. Ellis showed a series of slides, indicating the technique of the methods employed; also a slide to show the type of X ray burn of the skin, which while healing perfectly might be thought by the uninitiated to indicate an overdose—being in reality the dose aimed at. He also quoted Döderlein's figures in operable cases which showed 80 per cent. five-year cures after complete radiation, as compared with 46 per cent. after operation. They afforded adequate reason for Döderlein having given up the operative procedure.

Dr. E. A. GERRARD drew attention to the excellence of the results in a series of cases which had been handled entirely by gynæcologists, without resort to their radiological colleagues. Was this a point of importance—even significance? He thought so, particularly as there was a growing tendency in certain areas for the general practitioner to refer malignant cases directly to the radiologist. Was this in the best interests of the patient? The radiologist could hardly be expected to have had a wide experience in a special branch like gynæcology. The diagnosis in carcinoma of the cervix, particularly of the endocervical type, was not always easy, and the correct application of the radium was liable to present real difficulty unless the operator was regularly engaged in vaginal surgery.

Mr. J. E. STACEY advocated Wertheim's operation in first-stage and early second-stage cases—along with radiation, as this precluded the ill-health from cystitis, proctitis, &c., which was liable to follow if radiation alone were employed. He believed that coöperation between gynæcologist and radiologist was advisable; the gynæcologist should diagnose the condition and the radiologist should decide the dose and apply the treatment.

Prof. MILES PHILLIPS also advocated the coöperation of gynæcologist and whole-time radiologist. He laid stress on the necessity of doing all one could to prevent carcinoma by the ruthless removal of the cervix whenever it was found in a badly damaged or chronically infected condition. The fact that the annual mortality-rates showed, for a number of years, a steadily falling death-rate from cancer of the uterus, whereas that from cancer in all other organs was increasing, was at least highly suggestive that this method of preventive treatment was becoming effective.

Dr. I. A. B. CATHIE spoke of the grading of tumours as an aid to prognosis. He was inclined to disagree with the prevalent idea that the columnar-cell type of growth was resistant to irradiation.

Prof. DOUGAL, in reply, said that Prof. Shaw and himself, recognising that their series was a small one, realised that they might have been fortunate in their results. He agreed with Mr. Todd that there was now no justification whatever for the Wertheim operation. He had seen one case in which application of radium had been followed by a fistula, but the dose given had been unduly high—11,000 mg.-hours. He held that coöperation between surgeon and radiologist was undoubtedly desirable, though the dose for carcinoma of the cervix was largely standardised. He did not think that a radiologist was the best person to apply the radium in this region, for even

an experienced operator sometimes found great difficulty in advanced cases with the insertion of the intra-uterine portion of the dose.—Prof. DOUGAL agreed with Dr. Cathie that the columnar-cell type of growth was proving to be less resistant to radium than had been thought in the past.

Naegele Pelvis

Dr. CLANCY reported the case of a 6-gravida who had had two stillbirths and three live children, all by instrumental deliveries. After the first delivery there had been paralysis of the left leg. She was admitted to hospital at the thirtieth week and on vaginal examination the membranes were found to have ruptured. The cervix and vaginal vault exhibited marked laceration indicating severe trauma at previous deliveries, and in view of this fact, it was decided to have a radiogram taken. This revealed a Naegele pelvis, of which there had been no indication by vaginal or other examination. The external appearance of the patient was also normal, and neither figure, gait, or carriage gave any suggestion of deformity. The following measurements were taken: interspinous, 8½ in.; intercrural, 9½ in.; external conjugate, 6½ in.; external obliques, 7 and 7½ in.; posterior superior spine to symphysis on each side, 6½ in.; spine of last lumbar vertebra to anterior superior spine, 6½ and 6½ in. On examination of the patient's back a definite bony lump was found over the sacro-iliac joint on the affected side. The striking feature of these cases was the difficulty in diagnosis; for apart from the bony lump there was nothing to indicate the serious deformity. The customary measurements, as stated by Whitridge Williams, merely suggested a justo-minor pelvis. Dr. Clancy felt that there was much to be said for having a radiogram taken wherever there was a history of former dystocia.

The PRESIDENT spoke of the rarity of spontaneous delivery in the type of case, also the high mortality recorded—Litzmann, 22 deaths in 28 cases.—Dr. J. W. BRIDE referred to the temporary paralysis of the leg from which the patient had suffered after the first delivery. It was remarkable that nerve injury should be so rare even after difficult instrumentation.—Prof. PHILLIPS said that this case showed the desirability of all maternity hospitals being provided with an X ray apparatus.

Malignant Ovarian Tumours and Hysterectomy

Mr. C. H. WALSH showed a specimen of calcified fibroids associated with malignant pseudomucinous ovarian cyst and adenocarcinoma of the body of the uterus with hæmatometra.

The patient was a nullipara, aged 66, who had passed the menopause at 52, since when there had been no vaginal discharge. She had been perfectly well until the day before she was admitted to hospital for severe abdominal pain and vomiting. The pulse, respiration, and temperature were normal, but abdominal palpation revealed a hard mass in the right iliac fossa and a cystic tumour in the left side of the abdomen. The cervix felt normal and there was no vaginal discharge. In view of a possible diagnosis of carcinoma of the colon, a barium meal was given, and on radiography a calcified mass was seen in the right iliac fossa, which had the appearance of a calcified fibroid. The cystic mass was thought to be ovarian in origin, and a laparotomy was performed. There was no ascites. The uterus contained multiple fibroids, and the large calcified tumour seen in the radiogram was found to be a pedunculated fibroid, arising from the right side of the fundus uteri. The swelling on the left side was an ovarian cyst the size of a

football. Total hysterectomy with bilateral salpingo-oophorectomy was performed, and on incising the uterus after operation the surgeon was surprised to find it full of malignant growth and distended by about 6 oz. of blood-stained fluid. The tubes were also found to contain several malignant nodules, but in no instance had the growth reached the peritoneal surface. The ovarian tumour proved to be a papillary pseudomucinous cyst adenocarcinoma.

Prof. FLETCHER SHAW, in advocating removal of the uterus in all cases of malignant disease of the ovaries, recalled a case which supported the view that the growth in the uterus was secondary to the one in the ovaries. The patient, aged 39, had had double ovarian carcinomata—each the size of an orange and both free from adhesions. These were removed and the uterus retained; but after the operation the patient had amenorrhœa for 18 months, succeeded by irregular and increasing bleeding. About two years from the first operation, the irregular hæmorrhage having been present for about six months, panhysterectomy was performed and an advanced carcinoma was found in the interior of the uterus. If the growth had been primarily in the uterus it was hardly possible for it to have remained quiescent and for the woman to have 18 months' amenorrhœa after the removal of the ovaries. If, as seemed more likely, the uterine growth was secondary to the ovarian, it must have been in an early stage when the ovarian growths were removed and have progressed slowly, for hæmorrhage began only 18 months later. The first operation was in 1912 and the second in 1914, and the patient was alive now, 24 years after the first operation.

Dr. ELLIS thought it an advantage when operating on these cases to leave the uterus with a view to subsequent radium therapy. He quoted a recent paper by Schroeder giving results of treatment of a relatively large number of cases of proved malignant disease of the ovary treated by radiation. Schroeder divided his cases into three groups: (1) those in which he was able to remove all visible growth; (2) those in which most of the visible growth was removed; and (3) those in which only a portion of the growth was removed for biopsy. The five-year cures were 66 per cent. in Group 1 and 16 per cent. in Group 2. The latter was, however, subdivided into two sub-groups. In first of these the uterus was not removed, so that it was used afterwards for intrapelvic application of radium in addition to the X ray treatment which all the patients received; the five-year survival-rate was 25 per cent. In the second, in which the uterus was not left and therefore radium was not applied, there were no five-year survivals. These figures indicated the advisability of supplementing operation with radium as well as X ray treatment, with the corollary that it was advisable to leave the uterus in position if all obvious growth was removed.

Mr. BURNS referred to a case in which a malignant ovarian tumour, the size of an orange, was removed and the patient had no symptoms for two years. After this time, uterine hæmorrhage occurred, and curettage showed a growth similar to that of the ovary. A dose of 2000 mg. hours of radium was given, and the patient had no further symptoms. Curettage 18 months later revealed merely fibrous tissue.

Mr. C. R. MACDONALD showed a specimen of acute torsion of a hydrosalpinx in pregnancy.

Dr. BRIDE reported two cases of unusual Ectopic Pregnancy.

REVIEWS AND NOTICES OF BOOKS

An Enquiry into Prognosis in the Neuroses

By T. A. ROSS, M.D., F.R.C.P., sometime Medical Director, Cassel Hospital for Functional Nervous Disorders. London: Cambridge University Press. 1936. Pp. 194. 10s. 6d.

THIS book presents a serious attempt to find out what really happens to patients who have been treated for neuroses. The after-histories of nearly 1200 patients treated at the Cassel Hospital have been investigated, and, as the first cases were treated in 1921, many have now been followed up for over ten years. Forty-five per cent. of all the cases were well one year after discharge; 25 per cent. were improved; 19 per cent. had not benefited, while the remaining 11 per cent. were lost sight of. Of 850 patients, investigated five years after discharge, 502 were lost sight of, 290 were well, and 58 were improved. In 1934, only 134 of the 1186 patients were known to have relapsed. Dr. Ross states that many patients who reported themselves as improved in the earlier years after leaving hospital reported themselves later as being well. The average duration of stay in hospital increased gradually from 2.3 months in 1921 to 7.2 months in 1933. The best results were obtained in 1930 when the average duration of stay in hospital was 4.4 months. In this year 63 per cent. of the patients were well a year after discharge. Dr. Ross also reports his investigations into the prognosis as regards suicide and insanity. Patients known to have committed suicide numbered 7; and 23 patients were known to have become psychotics. The names of the "lost" patients were sent to the proper authority, and it was found that 10 had been certified and 16 had been received into mental hospitals as voluntary patients. From these figures Dr. Ross concludes that the prognosis with regard to becoming insane is good.

Dr. Ross's writings on the neuroses make a general appeal, for he uses simple language which all can understand. His methods of treatment are also simple and can easily be made use of by the practitioner. He is strongly critical of the Freudian school in their insistence on the need for prolonged analysis; whereas the Freudian analysts maintain that simple methods, such as Dr. Ross advocates, only cause temporary relief.

The good results here reported suggest that the methods Dr. Ross advises result in permanent cures in a high proportion of cases of neurosis; they should be studied with care.

Pathology of Internal Diseases

Second edition. By WILLIAM BOYD, M.D., M.R.C.P. Edin., Professor of Pathology in the University of Manitoba; Pathologist to the Winnipeg General Hospital, Canada. London: Henry Kimpton. 1935. Pp. 904. 45s.

To bring this book up to date has involved 25 additions to the text, though only four years have elapsed since the first issue, and the revision or complete rewriting of 13 sections. The descriptions of the anemias, the diseases of the endocrine system, and pulmonary disease, among others, have had to be considerably altered. In spite of all this new material the volume has been increased by only 16 pages. This feat has been accomplished by the introduction of small type for some of the less common conditions and by shortening the chapter sub-

headings. We have here an attempt to bridge the gap which often exists between medicine and pathology, and the book should certainly help the student. The post-graduate student in particular will appreciate the references to recent work, which are now arranged under subject headings. A surprisingly large store of sound, well-balanced teaching is to be found in readable form in these pages.

1. Foundations of Short Wave Therapy

By Dr. WOLFGANG HOLZER, Assistant in the Physiological Institute of the University of Vienna; and Dr. EUGEN WEISSENBERG, Medical Superintendent of the Short Wave Section of the University Clinic for Nervous and Mental Diseases in Vienna. Translated by JUSTINA WILSON, F.R.C.P. Edin., D.M.R.E. Cantab., and C. M. DOWSE, B.Sc. Lond., A.M.I.E.E. London: Hutchinson's Scientific and Technical Publications. 1935. Pp. 228. 12s. 6d.

2. Short Wave Therapy and General Electrotherapy

Illustrated. By HEINRICH F. WOLF, M.D., Consultant, Department of Physical Therapy, Mt. Sinai Hospital. New York: Modern Medical Press. 1935. Pp. 96. \$2.50.

3. Néodiathermie à ondes courtes

By Dr. HENRY BORDIER and Dr. T. KOFMAN. Paris: J. B. Baillière et Fils. 1936. Pp. 139. Fr. 24.

1. IN our review (THE LANCET, 1935, ii., 1125) of the German original we noted that here is to be found the best presentation of the technical aspect of ultra-short waves available in book form. The translator of this section has kept closely to the text—a highly desirable feature where physical facts and theories are detailed, even though it leads him to speak of the principles of electric circuits as "connexion theory." Accuracy has been maintained throughout and the rare misprints lead to no confusion.

The second section, devoted to therapy, is relatively short. The translator has expanded it by printing the descriptions of cases in the same type as the general text, whereas in the original smaller type was used for clinical examples. Some redundancies have crept in: an "adipose" woman is translated as a "stout corpulent" woman, but the fact that the translation is more free has made it also more readable. This therapeutic section would have been improved if Dr. Wilson had felt free to make some additions from her own experience of the method. Every practical worker in short-wave therapy should possess a copy of this book.

2. Dr. Wolf's book of drawings show types of electrodes and methods of application to the various diseased organs. Practical hints are interspersed, some of which are aimed, wisely, at preventing further damage to the patient. The author continues to maintain a preference for the diathermy machine for treating whole limbs, while the valve apparatus is appropriate for the treatment of selected cases of acute local inflammation.

3. It was in France that the therapeutic application of high-frequency currents originated, for it was d'Arsonval, in 1891, who made possible the use of diathermy. This little book gives an account of the theory and practice of diathermy and of ultra-short

waves which is well balanced, concise, and yet very readable. French machines of commercial type are included and some space is devoted to the biological effects of high-frequency currents.

A Synopsis of Physiology

Second edition. By A. RENDLE SHORT, M.D., F.R.C.S., Professor of Surgery, University of Bristol; and C. I. HAM, M.B., F.R.C.S. Edin., late Demonstrator in Physiology in the University of Bristol. Edited by C. L. G. PRATT, M.Sc., M.D., Lecturer in Physiology, St. Thomas's Hospital Medical School. Bristol: John Wright and Sons Ltd.; London: Simpkin Marshall Ltd. 1936. Pp. 312. 10s. 6d.

THIS book should be an excellent tonic for students who complain that physiology is "so indefinite." It is crammed with facts from beginning to end, and even the reasoning is tabular. It is not, of course, intended by the authors to be used alone as a text-book, although it contains more information than many text-books; it is a present to the student rather than a contribution to physiology. A dangerous present, perhaps, for it would be a peril to any student into whose hands it fell more than three months before his examination. The reason for this is that the authors have done their work surpassingly well, so that the reader of the book does not require to think at all: this has all been done for him. If he has not done his own thinking previously he will inevitably bend all his energies to memorisation and his knowledge will be sterile. Physiology is a subject to be understood rather than learnt; it is the medical student's training in how to reason about the human body, a pursuit which will occupy him for the rest of his active life. Nevertheless, examinations must be passed, and there could be no better form of revision than reading through this book. It is an exhaustive summary, accurate in the main details, and the subject is not "simplified." The sub-headings of the various sections provide what no larger book can—namely, a bird's-eye view of the subject matter and a gratifying illusion of finality. It is strongly to be recommended to those who feel their confidence ebbing before an examination. It should prove even more useful to teachers of physiology, not because they will learn very much from it, but because it will help them to present their lectures in an orderly fashion by suggesting a plan. Knowledge does not always go hand in hand with the power of exposition, and no teacher need be ashamed of making use of the painstaking analysis whose results are presented in this synopsis.

Lectures on Diseases of Children

Seventh edition. By ROBERT HUTCHISON, M.D., LL.D., F.R.C.P., Consulting Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond-street. London: Edward Arnold and Co. 1936. Pp. 452. 21s.

THERE can be few text-books that have provided generations of medical students with more agreeable or serviceable reading than Dr. Hutchison's famous lectures. The seventh edition of a volume so well known requires little comment. The lecture dealing with chronic constipation in infancy and childhood, and part of that concerned with pink disease, have been rewritten, but apart from this there have been only minor alterations. The style conveys a peculiarly personal quality, and the matter is compact of sound

judgment. The author specifically disclaims any intention of writing an exhaustive treatise on children's diseases, and the student must seek elsewhere for detailed descriptions of modern methods of diagnosis and treatment. For a wholesome reminder of the outstanding importance of clinical observation, the student can do no better than study Dr. Hutchison's lectures.

British Journal of Children's Diseases

(Vol. XXXIII., January-March.)—In an address entitled *Farrago Pyretologica: a Medley on Fevers*, recently delivered before the Nottingham Medico-Chirurgical Society, Dr. J. D. Rolleston stated that the study of fevers was so full of interest and importance that he had ventured to revive the term used in its Greek form by Richard Morton in 1692 for the title of his work on fevers. During the 35 years that Dr. Rolleston had been in fever practice he had witnessed a remarkable change in the incidence and severity of certain diseases, such as scarlet fever, small-pox, and enteric, as well as the appearance of new diseases such as encephalitis lethargica, encephalitis following measles and varicella, and summer typhus. New specific methods of diagnosis and treatment had been introduced, while others, especially the therapeutic use of alcohol, had been superseded or largely replaced. After discussing the Dick and Schultz-Charlton tests, and active and passive immunisation against scarlet fever as well as the antitoxin treatment, he maintained that four weeks' isolation was amply sufficient for an uncomplicated case, as had been recommended in a Ministry of Health report in 1927, though this recommendation did not seem to be generally known to the profession or the public. Chicken-pox was not always a trivial disease as it might give rise to serious and even fatal complications, and he had seen 6 deaths from it. He had never seen two attacks of measles in the same individual, nor a severe attack of rubella apart from one complicated by appendicitis and another by purpura hæmorrhagica. Like most observers with a long and intimate knowledge of the acute exanthemata, he had never encountered "the fourth disease," and declared that this term was more applicable to erythema infectiosum, sometimes known as "the fifth disease." It was still necessary to insist on making the diagnosis of diphtheria on clinical grounds, for he was constantly seeing cases in which valuable time had been lost, often with fatal results, because the practitioner did not send the child to hospital or inject antitoxin before he had received the report on the throat swab.—In a paper on the Mantoux Test in Children with Special Reference to Home Contacts, Dr. G. Gregory Kayne stresses the importance of some simple rules to guide the clinician in the use of the Mantoux test, and describes some points in the technique, routine procedure, and reading of the test. The significance of a positive and negative reaction in children is also described. Lastly, the usefulness of the test in the examination and handling of home contacts is considered.—Dr. Alair Chand, professor of medicine at the Amritsar medical school, contributes a paper on Chronic Jaundice in Three Brothers with Hypertrophic Cirrhosis of the Liver and Infantilism. The clinical features tallied in almost all respects with those of Hanot's cirrhosis. In the first case, that of a man aged 24, who died, signs and symptoms of portal cirrhosis appeared in addition to those of biliary cirrhosis a few months before death. No biopsy nor necropsy could be obtained. The other two brothers aged 16 and 12 were still alive.—In a paper entitled *A Seventeenth Century Cure for Rickets*, Dr. W. J. Rutherford comments on Sir Thomas Browne's statement in his *Account of the Birds Found in Norfolk* that about Norwich the livers of rooks were used for the cure of rickets.—The abstracts from current literature are devoted to treatment.

THE LANCET

LONDON: SATURDAY, MARCH 28, 1936

THE MIDWIVES BILL

At the opening of the Parliamentary session last December the Speech from the Throne referred to the need of improving the maternity services and promised legislation whereby local authorities, in coöperation with voluntary associations, would provide an organised service of salaried midwives. The pledge is redeemed by the Midwives Bill which the Minister of Health has now presented. It embodies the main points recommended by the Joint Council on Midwifery—the principle that every maternity case should be nursed by a qualified midwife, the prohibition on unqualified persons nursing maternity cases for gain, the establishment by local authorities of a salaried service in all areas not already served by salaried midwives, and the grant of compensation or pension to all midwives who either are not accepted for salaried service or are found unfitted by reason of age or infirmity. County and county borough councils (and in some cases county district councils) are by statute the "local supervising authorities." It is to be their duty to secure within their areas a sufficiency of certified midwives to attend on the parturient woman in her own home and to act as maternity nurse for at least ten days after childbirth. The authorities are to arrange with welfare councils and voluntary associations for the whole-time service of the necessary personnel or else to employ midwives direct. They are to formulate proposals in consultation with local organisations of medical practitioners and of midwives and with welfare councils and voluntary associations, and the resultant scheme is to be submitted to the Minister within six months of the Bill passing into law. Before a local authority first engages midwives for employment, it must advertise the prospective appointments and the proposed salaries and conditions. As every practising midwife in the district must receive this information, there is reasonable hope that as many as possible of the salaried posts will be filled by local midwives previously in independent practice—a course which will simplify the transition and alleviate hardship. Each authority is to fix scales of fees for the services of midwives and maternity nurses, and it will be charged with the duty of recovering the fees from the patient or her husband, subject to a discretionary power to remit in view of the financial circumstances of the particular household. The additional cost of the scheme to the ratepayers will be borne in part by the Exchequer through the mysterious but efficient formula of the block grant adjusted to local needs and population. As the Minister has power to reduce the grant in case of inefficiency,

the local supervising authority itself comes under supervision.

While the general standards of midwifery are being thus improved to the national advantage, it would be a pity if the national conscience had cause to feel uneasy over the fate of the midwives at whose expense the change is made. With the goodwill of the local authorities existing midwives can be absorbed in the new scheme, but there will remain a residue for whom the future holds anxiety. It is said that there are about 60,000 midwives on the roll and that only about a quarter of these are in actual practice; of this quarter roughly half are in salaried posts under voluntary nursing associations or otherwise, while the other half are practising independently. What with financial stringency, the fall in the birth-rate, and the increasing readiness of women to go into hospitals for their confinements, the midwife's calling is overcrowded, although as in other callings there is room for women of the best type. The Bill proposes to remedy this superfluity by the double process of buying out and weeding out. Under Clause 5 the midwife who surrenders her certificate within three years will be compensated with a sum equal to three times her average net annual emoluments; a midwife deemed incapable of efficient service by reason of age or infirmity of mind or body will be required to surrender her certificate (subject to a right of appeal to the Minister) and, on surrender, will be entitled to receive a sum equal to five times her average net annual emoluments. The number of women who, under these two processes, will be eliminated from practice is officially estimated at less than 3500. When due allowance has been made for a frugal reluctance to subsidise the so-called inefficient out of the public purse, the fact remains that most of these women paid for their own training and all have played their modest part in serving generations past, present, and future. The women who disappear from practice under Clause 5 can never be restored to the roll; they will commit a criminal offence if in future they act as midwives or maternity nurses. Section 3 of the Dentists Act was far more tender to the existing practitioner. Statistics, so far as available, indicate that a large majority of midwives have been earning less than £100 a year; one-third of them earn £50 or less; only one in seven earns £200 or more. When bad debts and professional expenses, food, and rent are deducted from these gross totals, the net annual sum (on which the compensation will be computed) is exiguous. Some 550 midwives in independent practice, it is believed, are over 60 years of age. They cannot have put by much against a rainy day. The Bill not ungenerously accepts the principle of compensation for this disappearing class of workers; its individual application will be scrutinised anxiously by those concerned.

As for the rest of the Bill, there is an excellent proposal that rules framed by the Central Midwives Board may require midwives to attend periodical courses of instruction arranged by the local authority of the district, and may also permit the Board to grant diplomas to midwives presenting

themselves for examination in the teaching of midwifery. The Minister of Health may prescribe the qualifications of persons appointed by a local authority to supervise the midwives practising within the area; nobody is to be appointed who does not possess the prescribed qualifications. Lastly there is a significant little clause which will give the Minister a power denied to him by the Court of Appeal last year. Under Section 14 of the Midwives Act of 1918 a midwife in cases of emergency can call to her assistance a medical practitioner. The Act says the local authority shall pay the medical practitioner a fee on a scale fixed by the Minister. In the Monmouthshire County Council case it appeared that not only did the Minister fix the scale of fees as Parliament said he might, but he also added conditions. The conditions involved the possibility that a doctor might do the work and yet not get the fee. The Court of Appeal found no power in the section for the Minister to do anything but fix a scale. Four doctors, advised by the two medical defence societies of which they were members, successfully claimed their fees in spite of the Minister's conditions. There was talk of the Minister taking the case to the House of Lords; he has found a simpler method of getting his way.

HYPERPYREXIA IN THE TREATMENT OF GONOCOCCAL INFECTIONS

DURING the past few years much experimental work has been done, chiefly in the United States, on the treatment of certain infections by physical methods which produce an increase in the general body temperature over a period of hours. Some have modified the old radiant heat bath, while others induce pyrexia by means of diathermy, short (wireless) waves, or inductothermy. It was evident from the views expressed at the Conference on Fever Therapy held at Dayton, Ohio, last year, that opinions differ greatly about the best type of apparatus, the most effective methods of applying the treatment, and the pathological conditions in which benefit may be expected. Nevertheless on some points there is a remarkable unanimity, and reports from many quarters show that the results in gonococcal arthritis may be excellent and even spectacular. Dr. NEYMANN,¹ of Chicago, speaking at the Royal Society of Medicine last April, said he could find no exception to the widespread belief that electropyraxia is the treatment of choice in such cases, and the same phrase is used by KENDELL, WEBB, and SIMPSON,² who report good results in 31 cases of gonococcal arthritis treated in the Kettering hypertherm—an air-conditioned cabinet in which the humidity can be controlled.

Among the forms of therapy now adopted is the combination of general hyperpyrexia with local application of the diathermy current to the pelvic focus of infection; and BIERMAN and

LEVENSON³ regard this mixture of old and new methods as a definite advance. Their practice is to place the patient in a water bath at 100–102° F. and gradually raise the temperature to 107–108°. By this means it is possible, within an hour, to bring the rectal temperature up to about 105° F., after which pyrexia of about 105.5° can be kept up without difficulty for five or six hours by transference to a bed covered with a hood made of insulating material and containing a battery of 60-watt electric light bulbs. Additional pelvic heating is obtained by the diathermy current, the active electrode (water-cooled if necessary) being inserted into rectum or vagina and the dispersive electrode being applied in four sections covering a wide area of skin. In this way, it is found, a temperature of 111° can be maintained in the pelvis for as long as 3½ hours. Of 16 patients treated (8 male and 8 female), 13, it is stated, had complete restoration of function, and in the other 3, who had already suffered irreversible joint changes, some improvement was recorded. The women required an average of 2.1 treatments the men 3.5, and the intervals between treatments varied from two to thirteen days. The best results were obtained in early acute cases.

The use of heat in the treatment of metastatic complications of gonorrhœa is by no means new, and has been practised in various forms for many years. Hence the conservative may argue with some reason that hyperpyrexia is merely a variation on an old theme; and there is no doubt that excellent results are commonly obtained by well-tried methods, without the additional discomforts and risks involved in exposure to high temperatures for a long period. Nevertheless there is at least one feature of these recent investigations which deserves close attention—namely, the frequent reference made to the rapidity with which gonococci disappear from the discharges and purulent secretions themselves subside when these more drastic methods are employed. STUHLER⁴ says that urethral discharge sometimes ceases, and smears are often negative for the gonococcus, after the first session of fever therapy, and he makes the remarkable claim that fever therapy for gonococcal infections is one of the greatest advances made in the last fifty years—an advance “of even greater importance to the clinician than was the discovery of the gonococcus by Neisser in 1879.” In their latest paper⁵ STUHLER and his colleagues review the results of treating gonorrhœa with the Kettering hypertherm during a period of nearly two years, and are able to say that of 76 patients who completed the treatment 68 were cured and 7 were improved, while only 1 failed to respond. The condition was in 36 cases an uncomplicated urethritis; in the remaining 40 there was a complication in addition; but the infection never spread in consequence of treatment. Two-day intervals were allowed between sessions of fever therapy, and as a precautionary

measure the treatment was always twice repeated after the signs and symptoms had disappeared; but most of the patients required only five or six sessions for cure. Better results were obtained as technique improved and these latest data in no way modify the optimism of earlier reports. If the claims put forward are justified—if means can really be found to reduce the weeks of mental stress, incapacity, and danger associated with the acute stages of gonorrhœa to days or even hours—then STUHLER'S words are certainly not an overstatement. Meanwhile in this country, so far as we know, there has not yet been any organised attempt at investigation on similar lines. An inquiry of this kind might well commend itself to public health authorities and those engaged in the systematic treatment of venereal diseases in clinics throughout the country.

ACADEMIC FREEDOM

WE print elsewhere (p. 739) Lord RUTHERFORD'S account of the work done by the Academic Assistance Council and of how it is proposed to carry on such part of the work as seems likely to require to be done in the future.

The Academic Assistance Council consists of 36 men and women eminent in various fields of scholarship and science; 13 of them are fellows of the Royal Society (including the president and two past-presidents) and 6 are either members of the medical profession or research workers in the medical sciences. "Intellectuals" and "professors" are sometimes accused of showing little ability in practical organisation; the work done by this body of "intellectuals" is an instructive commentary upon that popular opinion. From the beginning they had to deal with a problem which stirred popular feeling, exciting generous and selfish emotions in about equal proportions. On the one hand a tale of cruelty and oppression

in foreign countries never fails to arouse sympathy. Less literary ability than was at the command of the Council would have produced a story fit to be adorned with headlines in the daily and evening press. It would have been a convenient safety valve for emotion, and, by wounding foreign susceptibilities, have postponed for ever any hope of reconciliation. On the other hand, the pecuniary rewards of learning and science in this country are not so abundant that the provision of opportunities for foreigners, who may be competitors for posts to which home-bred scholars looked forward, can be examined with complete impartiality. The dangers could have been avoided by the issue of completely colourless statements and emphasis upon the temporary character of much help given. The result would have been general indifference. The Council have had the wisdom and skill to avoid wholly the dangers without lapsing into a policy of mere hand-to-mouth charity. They have, without using language which could give reasonable offence to foreign governments or nationals, made plain the tragic circumstances of many who have deserved well of all who value intellectual liberty, and in their practical policy have given no grounds for local jealousy. An organisation has now been created fit to cope with the difficulties of the future and all will wish success to the proposal to put it upon a permanent basis.

All will hope, not least the members of the Council, that the time will come when the interest of the Society for the Protection of Science and Learning will be purely historical. Unfortunately the state of the world holds little prospect that the hope will be realised in the near future, and we trust that the new society will be generously supported by members of a learned profession which in its long history has too often suffered from the want of intellectual freedom.

ANNOTATIONS

MEASLES IN LONDON

ATTENTION was drawn on p. 692 of our last issue to the rapid increase in the number of cases of measles under treatment in the fever hospitals of the London County Council. The total number of patients in the measles wards is now over 3000. During the week ended March 24th 964 fresh cases of measles were admitted, and on one day (March 23rd) as many as 178 cases. The number under treatment at one time has not yet reached the maximum of the last epidemic when, on a day in April, 1934, 3696 measles patients were being cared for in these hospitals. In that epidemic, notable prevalence, as reflected in the occupied beds, commenced a fortnight earlier than upon this occasion, and although the epidemic must be approaching its climax, it is not possible to say that this has in fact been reached. The later start is all to the good, because it implies more favourable seasonal conditions during the phase of maximum prevalence; we learn that the incidence of broncho-pneumonia is not notably high, and that in this respect the epidemic compares well with the last. In 1933-34, concurrently with measles, diphtheria and scarlet fever were also very prevalent. There is at the present time no undue prevalence of

these other common infections of childhood, and this is fortunate because, although the London County Council possess ample reserves of accommodation, there is a shortage of nursing and domestic personnel. Now that the need for temporary additional assistance has been made known in the press it will doubtless be met, although this authority is not alone in experiencing difficulty in obtaining nursing and domestic staff at the present time.

VITAMIN B₁ BY INJECTION IN TREATMENT OF NERVOUS DISEASES

At a meeting of the Edinburgh Pathological Club last week Dr. W. Ritchie Russell read a paper¹ on the parenteral administration of vitamin B₁ in polyneuritis and other conditions. He obtained supplies of the vitamin from Messrs. Hoffmann-La Roche for clinical trial and used them in the treatment of diseases in which there was evidence of degeneration of the peripheral nerves. Cases of chronic progressive polyneuritis, alcoholic neuritis, and subacute combined degeneration of the cord were treated. All of them showed peripheral sensory loss of the glove

¹ To appear in May issue of the *Edinburgh Medical Journal*.

and stocking type, and Dr. Russell found that injection was followed within a day or two by shrinkage of the area of sensory loss. As the treatment was continued the anaesthesia and weakness in the limbs quickly diminished, and he believes that the improvement occurring rapidly in the nerves that were least degenerated is similar to the rapid recovery obtained by injecting the vitamin in animals suffering from B₁-deficiency. The longer nerves, which are severely degenerated, can of course recover only gradually. In some of the cases reported the patients had been taking vitamin B₁ by the mouth previously without any good effect, and the striking improvement after parenteral administration suggests that in such persons the vitamin is destroyed in the alimentary canal or is for some other reason not absorbed. The two advantages of injection to which Dr. Russell drew attention are (1) that it overcomes this possible "conditioned deficiency" due to failure in absorption, and (2) that it produces a quick response which is of value in diagnosis because it demonstrates that the patient is really suffering from a lack of the vitamin. Anorexia of long standing sometimes responded to a single dose.

INCAPACITY AND LIGHT WORK

THE insurance doctor is constantly called on to decide when a patient who has been in receipt of sickness or disablement benefit should no longer be certified as incapable of work. It would of course be impracticable to place upon the expression "incapable of work" so narrow a construction as total inability to carry out any of the physical or mental processes that constitute work, and in the handbook for the guidance of approved societies the advice is given that an insured person should properly be regarded as satisfying the statutory condition of being "incapable of work" if he is in such a condition, through some specific disease or bodily or mental disablement, that an attempt to work would be seriously prejudicial to his health. Further, although a person who is admittedly unable for the time being to follow his ordinary occupation may not necessarily be rendered unfit for some other and less exacting form of work, he may properly be regarded as incapable of work if it appears probable that he will soon be able to resume his former work, and it would therefore be unreasonable to expect him to undertake any other form of work in the meantime. But if it becomes clear in the course of the illness that there is no reasonable prospect of his becoming fit for his ordinary occupation the society are advised to consider whether the man's physical and mental condition is such that he is capable of performing other remunerative work of such a character as a man of his training, education, and experience could reasonably be expected to undertake. If the man (or woman) can be so regarded benefit should not continue to be paid after the insured person has had a reasonable time in which to adapt himself for a new form of employment.

Here enters the problem of "light work." It is one thing to say the insured person is fit for light work, but it is another thing for him to be able to obtain it. And, as Dr. J. P. Steel points out in relation to compensation cases, the difficulty is greater when the labour market is overstocked. At the last panel conference the Insurance Acts Committee put forward a recommendation that where an insured person is considered by his doctor to be fit for work, but not fit for his former occupation, the doctor might give an indication to this effect in his next certificate by the insertion in the remarks column

of the words "(?) alternative employment." It had previously been proposed that when a patient was likely to be fit for some employment but was not likely ever, or for a long period, to resume his previous occupation, this fact might be indicated to the society in the form of an inquiry as to what action the society proposed to take in the particular case. This was regarded as open to objection as a possible infringement of professional secrecy. One difficulty in dealing with this type of case is that, when an insured person is permanently incapacitated for his ordinary work although no longer completely disabled, certain approved societies are apt to stop payment of benefit the moment the practitioner indicates his fitness for some kind of work. Other societies willing enough to deal with cases more liberally are met with the difficulty that in many areas there may be no alternative employment. An entry on a certificate, as was remarked at the conference, does not turn a blacksmith into a waiter. Dr. Steel is dealing specially with persons in the transitional stages between incapacity following an accident and complete recovery therefrom. But the provision of light work, or of alternative employment, is common to both problems.

REPEATED ABORTION

DURING the luteal phase of the ovarian cycle the uterine muscle loses its spontaneous contractility and becomes relatively insensitive to posterior pituitary extracts. From this it is deduced that the corpus luteum maintains the uterine quiescence that is essential for retention of the developing embryo during early pregnancy. Assuming that habitual and threatened abortion sometimes results from undue uterine motility various workers¹ have advocated the prophylactic or therapeutic use of the corpus luteum hormone progesterin in such cases. Finding that 1 rabbit unit of progesterin can inhibit human uterine contractions on the seventh day post partum, Falls, Lackner, and Krohn² have been giving 1 rabbit unit twice daily in cases of threatened abortion until the symptoms subsided or the patient aborted, and a similar dose twice weekly from the time of diagnosis of pregnancy until the 32nd week in cases of habitual abortion. In a series of 41 cases they report only 7 failures, and these results are in general agreement with those of other workers, though there is elsewhere a tendency to give more frequent doses, in the habitual abortion group, during the early months of pregnancy when this type of abortion is commonest.

Despite the success claimed for this treatment, however, there may well be other factors—excluding such organic causes as syphilis—responsible for habitual abortion; and of these a deficiency of vitamin E is possibly the most important. Attention was first drawn to this stable, fat-soluble vitamin, present in high concentration in wheat-germ oil, by H. M. Evans and K. S. Bishop in 1922. Lack of this factor in the diet of male rats results in irreparable degeneration of the germinal epithelium of the testis; in pregnant females it leads to death of the foetus; and though in non-pregnant females no degenerative changes have been found in the ovaries such animals are said to suffer from a transient, relative sterility. The interesting observation has also been made, by Hill and Burdet in 1932, that

¹ Wolfsohn, H.: *Med. Welt.*, 1932, vi., 1616; Weinzierl, E.: *Med. Klin.*, 1933, xxix., 563; Bishop, P. M. F., Cook, F., and Hampson, A. C.: *THE LANCET*, 1935, i., 439.

the "royal jelly," the food juice of the future queen bee, is an abundant source of vitamin E, whereas the food of the sterile working bee is lacking in it. In 1929, investigating the diets of 206 sterile women, D. Macomber found them lacking in fat-soluble factors, and noted that when this deficiency was rectified 40 of the women became pregnant. In this country Dr. Evan Shute³ has lately reported that the blood-sera of 70 per cent. of women aborting spontaneously displayed an abnormal resistance to proteolysis when exposed to tryptic solutions, and states that administration of vitamin E restored the normal proteolytic action of trypsin. In Canada Watson⁴ has succeeded in bringing pregnancy to term in 75 per cent. of a series of 43 cases of threatened or habitual abortion by treatment with vitamin E. And others report similar experiences.

What part this factor plays in the maintenance of pregnancy has not yet been explained. Apparently it has no direct influence on ovarian activity, for there are no demonstrable degenerative changes in the ovaries in its absence, nor, as has been shown by Saphir,⁵ will it produce cornification of the vagina if injected into castrated adult rats, or activation of the ovaries of infantile rats, or luteinisation of the ovaries of infantile rats previously sensitised with a follicle-stimulating extract. On the other hand, by injecting into oestrous rabbits extracts derived from vitamin E-deficient pregnant and non-pregnant rats, Rowlands and Singer⁶ have shown that such extracts are less able to cause ovulation than pituitary extracts from normal rats. This suggests that vitamin E helps to maintain the normal activity of the corpus luteum during early pregnancy, not by direct action on the ovary, but by stimulating the gonadotropic function of the pituitary. If this is so, then the essential cause of habitual abortion is relative deficiency of the corpus luteum hormone—a deficiency which might be rectified either directly by injecting progesterin or indirectly by giving vitamin E to encourage the pituitary to produce its luteinising factor, or by administering the luteinising hormone (prolan) of pregnancy urine.

SCURVY: OVERT AND LATENT

ADULT scurvy is so rarely seen in this country that there are few opportunities for its investigation. Such cases as occur are usually in food faddists or men living alone, and a typical example of the latter class is described by Drs. Archer and Graham in a paper we publish this week. The patient, an unemployed man, was living by himself on the tiny income of 17s. 6d. a week. He budgeted very carefully, but his total weekly expenditure on fruit, salads, and potatoes was only 4d. The potatoes were bought as chips and there was very little of them. Doubtless it was at this point that the "living alone" factor just tipped the scales; a larger amount of potatoes boiled at home would have saved the situation. The man was taken into St. Bartholomew's Hospital where a diagnosis of undoubted scurvy was made, and, in the course of his treatment, his misfortune was turned to good scientific account, the urinary excretion of ascorbic acid, before and after treatment, being studied by means of titration. The excretion before treatment was low (6-18 mg. daily), and addition of a daily dose of 187 mg. of ascorbic acid

as orange juice led to little rise in it during the next 10 days. In other words the patient's tissues were not yet "saturated." After 17 days the dose was increased to 281 mg. and the result was an immediate rise in excretion to 42 mg.; by the 21st it had exceeded 100 mg. Study of a second case confirmed these results and a comparison was also made with the values given by a healthy man eating plenty of fruit. The daily urinary excretion in the latter case was 40-50 mg., and administration of 400 mg. of ascorbic acid daily for 10 days produced an immediate rise in excretion to 262 mg. on the first day and to over 400 mg. on the second day—an excretion of over 90 per cent. In agreement with the results of this work is a study from the Vanderbilt University medical school in America.¹ Here the subjects of investigation were not suffering from scurvy, but were consuming diets of very varying vitamin-C content. Some showed urinary excretion of under 10 mg. daily and a number of under 20, while very few rose above 30. The percentage retention after a single large dose of about 600 mg. of ascorbic acid tended to vary inversely with the size of the previously observed urinary excretion, the majority retaining 80 to 90 per cent. The only three subjects who retained less than 60 per cent. and who could be regarded as "saturated" were the only three showing a previous daily excretion of over 40 mg. The contrast is very conspicuous, as illustrated by both these studies, and it is increasingly clear that knowledge of the daily urinary excretion of ascorbic acid, and of the response to a large test dose of the vitamin, is a valuable diagnostic datum in latent or overt scurvy.

MODERN VIEWS ON EVOLUTION

THERE are many grades of opinion among biologists on the question of the mechanism of evolution, ranging from that of the neo-Lamarckians whose faith in the inheritance of acquired characters remains unshaken in spite of the paucity of evidence in its favour, to that of the gene mutationists whose theory has been erected upon an imposing mass of experimental evidence from genetics and cytology. Prof. Walker attempts,² in a recent publication, to reconcile conflicting points of view and facts which have hitherto been difficult to fit into a single theory. After disposing of the Lamarckian theories he ranges himself on the side of the selectionists, but denies the wide application of the chromosome theory of heredity. The most important characters of organisms, he says, are not inherited alternatively and are therefore not borne on the chromosomes, which are responsible for the transmission of relatively insignificant features. The major characteristics must be represented in some other part of the cell. The original suggestion is made that changes may originate in the chromosomes and later be impressed upon the rest of the cell. "Mendelian" characters are thus the recently acquired ones, while older and more basic characters are those which show "blending inheritance." Prof. Walker is justifiably sceptical of the Mendelian explanation of blending inheritance by the postulation of a large number of factors, a procedure which could explain almost anything. He is not, however, always just to the opposing view, and has ignored recent work which tends to show that many "Mendelian" characters are only outward signs of more important physio-

logical characteristics, that the action of a gene is by no means fixed but depends upon the nature of the rest of the "gene complex," and that the chromosome theory of sex determination can be reconciled (at least theoretically) with the occurrence of the sex reversal. Many of the difficulties in accepting the complete chromosome theory, particularly those derived from a study of the protozoa, are well stated in this monograph, which is, however, too discursive for easy reading.

Dr. Hurst makes a contribution of a different kind. His book³ is written in a lucid style and is so well planned that no one can fail to follow the arguments. The gene and mutation theories are clearly presented with no mention of any facts which might lead to confusion or to doubt that the theories as at present conceived may apply to all aspects of heredity and evolution. The origin of life in "progenes" is discussed in a manner which almost gives the impression that the matter has already been proved whatever may be meant by the term "progene." That naturally occurring short-wave radiations give rise to mutations which are the basis of evolutionary change is suggested and later assumed in spite of much contrary evidence. This is a readable and entertaining book, but which might, however, mislead the ordinary reader by giving an impression that the basis of the mechanism of evolution is thoroughly understood, and that it is now only a matter of working out the details. Few biologists would claim such finality for the theories of to-day.

THE PERCENTAGE OF OXYGEN IN OXYGEN TENTS

IN order to raise the oxygen-content of the atmosphere of an oxygen tent it is customary to begin by turning on the by-pass so as to obtain a brisk flow from the cylinder. When the required percentage has been reached the stream is adjusted so that it covers the relatively small amount used by the patient, and also the loss by leakage—which varies according to the airtightness of the tent. In many oxygen tents it is intended that the leak shall be sufficient to give egress to the carbon dioxide produced by the patient, making the use of soda-lime unnecessary. It is not practicable to blow away all the carbon dioxide in this way, for the loss of oxygen would be excessive; but an accumulation up to 2 per cent. or more is often considered permissible. On the other hand, in the type of tent where soda-lime is used the absorption of carbon dioxide is so efficient, and the tent can be made so airtight, that the oxygen flow can be cut down to 3 or 2 or even 1½ litres per minute. Recently A. L. Barach⁴ has pointed to a possible disadvantage in the more open type of tent. He was called to see a child 9 years old in one of these tents suffering from bronchopneumonia. The child was as "blue as a serge coat"; the pulse-rate was 160 and the temperature 108° F. The oxygen concentration in the tent was 28 per cent. (the oxygen in the atmosphere being 21 per cent.). Using a second cylinder Barach increased the oxygen flow by 32 litres a minute until the percentage rose to 60. The child's colour immediately began to improve, the pulse-rate came down to 120, and the temperature gradually fell to 101°. The child, whose eyes had previously rolled upwards,

became conscious, and the breathing which had appeared terminal and very shallow took on a deeper and more vigorous character. In another hospital disappointment with oxygen therapy could be traced to the practice of giving 7 litres of oxygen a minute in a tent that "leaked like a sieve." In three other instances in New York Barach found that a flow of 30 to 40 litres was required to keep the concentration between 50 and 60 per cent. Somewhat similar observations in this country were described by Dr. E. P. Poulton in last week's *British Medical Journal*. In a tent of the more open type he found that the maximum value was 35 per cent., and sometimes a value as low as 25 per cent. was obtained.

The problem remains whether the advantage of doing away with soda-lime is counterbalanced by the extra consumption of oxygen necessary or whether the certainty of being able to reach an adequate percentage of oxygen with quite a small flow is worth the expense of the soda-lime used. Barach inclines towards a large flow of oxygen (6 to 8 litres) and an increased leak, while Poulton has emphasised the value of an airtight tent with a small flow of oxygen and the addition of soda-lime. But both concur in the importance of analysing the atmosphere of the tent; and the practice of certain manufacturers in saying that it is unnecessary to test the oxygen concentration if a certain flow (between 12 and 7 litres) is run in, is to be condemned.

TRIGEMINAL TIC

Dr. Wilfred Harris's experience¹ of the treatment of trigeminal neuralgia by alcoholic injection must be unique. He has notes of 1140 cases which he has treated in this way and has recently examined this material for the purpose of summarising some of the lessons to be learnt from it. He suggests that, in order to avoid confusion with other forms of facial neuralgia, the terms trigeminal tic and glossopharyngeal tic should be used for the paroxysmal form of neuralgia which affects these nerves. Analysis of the cases brings out the greater liability of the female sex to trigeminal tic, which Dr. Harris believes to be due to an irritative process at the periphery of the nerve concerned. Of the total number of cases, 748 occurred in women and 392 in men. In 61 per cent. the right side of the face was involved and in 39 per cent. the left side. Of the 60 bilateral cases (over 5 per cent. of the total) 80 per cent. were in women. The author's technique for the injection of the Gasserian ganglion is described in detail, and the importance of proceeding step by step, patiently waiting for the manifestation of the signs appropriate to each stage of the operation before going on to the next stage, is emphasised. Those who have watched Dr. Harris at work will remember that he prefers local anaesthesia in cases where the intelligent coöperation of the patient can be anticipated. Any motor paralysis which results from the injection generally passes off gradually after a period of three months, and even in bilateral cases there is little loss of the power of mastication. Dr. Harris's method of injecting the inner two-thirds of the ganglion where it is unnecessary to destroy sensation over the distribution of the third division of the nerve is well worth noting; it must require considerable practice before any operator can expect to achieve the same measure of success with this delicate manoeuvre as its originator can claim. Since 1926, when Dr. Harris drew attention to the occurrence of trigeminal tic as a complication

³ Heredity and the Ascent of Man. By C. C. Hurst, Ph.D., Sc.D., sometime Fellow Commoner and Research Student of Trinity College, Cambridge. London: Cambridge University Press, 1935. Pp. 138. 3s. 6d.

⁴ Jour. Amer. Med. Assoc., Feb. 29th, 1936, p. 725.

¹ Ann. of Surg., 1936, civl., 161.

of disseminated sclerosis, he has several times observed the occurrence of trigeminal tic and disseminated sclerosis in members of the same family. In some families there had been a familial tendency to trigeminal tic; in one no less than nine members in three generations suffered from the disease.

PROLONGED ANALGESIA

THE relief of intractable pain is always a major medical problem, and when the pain is chronic it is one that tests the resources of the practitioner to the utmost. Sometimes, of course, the pain depends on a local cause which is accessible to local remedies; for instance, the pain following many rectal operations is often of this description. Here much can be done by strict cleanliness at the actual operation to diminish the suffering which used to be regarded as an inevitable sequel to any operation on the rectum. Nevertheless, operations in this region are more often than not followed by pain, more or less severe, even to-day. Frequently opiates are employed to control it, but since the symptom is of purely local origin it ought if possible to be controlled by local measures. Some rectal operations are satisfactorily performed under local anaesthetics, but the analgesic action of these is usually brief, and they cannot readily be applied again to the wound. A local analgesic with prolonged action would therefore be a great gain, but it is no easy task to find one which is both effective and innocuous. Quinine and urea chloride, for example, though excellent for its lasting effect, is liable to produce sloughing. N. J. Kilburne¹ describes the investigation, experimental as well as clinical, of a number of analgesics, with the object of finding one which could be used locally and could produce long-lasting effects. This he claims to have found in Eucupin, a modification of quinine hydrochloride with urethane. This is also bactericidal, and is said both to relieve pain and keep down infection. It is applied by soaking cotton in a 0.75 per cent. solution and pressing it into the wound. Kilburne's experiments with oily substances have not led him to regard these with favour for prolonged action, but we believe that trials now in progress at a London hospital are giving more encouraging results.

THE GOAL OF EUGENICS

AN attempt to portray in simple but accurate language the main principles of eugenics and their application to social problems has been made by Mr. Huntington in conjunction with the directors of the American Eugenics Society.² It is an outgrowth of an original report of a committee of the American Eugenics Society, prepared under the direction of Prof. Irving Fisher, and it is intended for intelligent people who make no claim to scientific knowledge concerning eugenics. In a preface the author informs us that he has done his best to express the general sentiment of the group of directors as a whole, but modestly adds that he has doubtless given too much weight to his own views. It is questionable whether the book will be found of much service to medical readers. It is prepared in the form of a catechism containing 371 questions and answers. Many of these are worded in such a way as to apply primarily to American conditions. Much the most difficult task which to-day confronts writers on eugenics is to give a satisfactory account of the aims and methods of "positive" eugenics; of how, in other words,

to encourage the fertility of persons regarded as biologically well-endowed. The fact having been noted that rural communities have a higher fertility than urban, American eugenists advocate a back-to-the-land movement which they hope may be organised on a sufficient scale to affect the country's birth-rate. Such proposals are hardly applicable to this country. Like most eugenists, Mr. Huntington is concerned lest schemes for promoting fertility should act dysgenically by encouraging the reproduction of biologically inferior strains at the expense of biologically superior. In this connexion the reader will frequently encounter throughout the book phrases such as a "well-matured plan of eugenic selection" or "an adequate basis of selection" which will enable us to distinguish eugenically superior from inferior stocks. A 372nd question which many medical readers would like to ask the author is whether anyone has yet devised a workable and scientifically valid scheme of eugenic selection applicable to the average citizen; and if not, why the American Eugenics Society does not try to do so. Most people admit that a small proportion of grossly unfit persons can be distinguished, of whom it can be definitely said that they should not become parents. But in view of the limitless variety of physical, moral, and mental qualities which combine to constitute good and bad citizenship, it is far from obvious how we are to recognise the person who embodies these various qualities in such a way as to enable us to regard him as representing a eugenically average type. If an average type cannot be recognised, how are we to devise well-matured plans, and establish adequate bases, of eugenic selection designed to encourage the fertility of persons above that average and to discourage that of persons below it?

ARTHUR SHADWELL

THE death of Dr. Arthur Shadwell which occurred on Saturday last at a nursing-home at Richmond has removed from among us a distinguished authority on many social questions and an effective writer on social matters of the first importance. The son of a Yorkshire clergyman, he was educated at Uppingham where he acquired under Paul David a knowledge of and taste for music which never left him. He went to Oxford as an exhibitor at Keble, was a student at St. Bartholomew's Hospital, and having graduated in medicine practised for a time in Brighton, where he became assistant physician to the Sussex County Hospital. He proceeded to the Oxford M.D. and was elected F.R.C.P., but he soon retired from the active practice of his profession to use his academic and practical training to fine advantage in dealing with such great subjects as the temperance question, epidemiology, urban water-supplies—especially the London water-supply—the arguments for and against socialism, and the application of economics to political activities. As a special correspondent of the *Times* he made investigations into epidemics of cholera in Germany and Russia, and in 1909 he published under the title of *Industrial Efficiency* a large volume in which he recorded the results of his personal study of economic conditions in this country, on the Continent, and in the United States, a work which gained him the degree of LL.D. Birmingham. Ten years ago he wrote an excellent handbook entitled the *Socialist Movement*, in which he was able to display his first-hand familiarity with much of what he discussed, his singularly fair attitude of mind, and his wide acquaintance with social history. The FitzPatrick lectures delivered before the Royal College of

¹ Surg., Gyn., and Obst., March, 1936, p. 590.

² *To-morrow's Children: The Goal of Eugenics*. By Ellsworth Huntington. New York: John Wiley and Sons, Inc.; London: Chapman and Hall Ltd. 1936. Pp. 139. 6s.

Physicians of London in 1925 and 1926 proved his classical learning. He was opposed to the State management of industry as advanced by the advocates of socialism, but he was able to give the authority for his arguments, either derived from his own work or that of others, and his appeals for reforms gained added force from his reasonableness. Through his long and distinguished connexion with the *Times* and the historic and literary value of his books, Shadwell became an authority in many provinces of political economy. If he wrote more as a philosopher than a doctor his medical training was always at the back of his arguments.

THE POSITION OF CHIROPODY

THE prosperity of the Incorporated Society of Chiropractors was emphasised at the recent annual dinner of the society noticed in another column; and from the mouths of the speakers it could be gathered how wise the attitude of the medical profession had been in regarding the therapeutics of the foot as a definite branch of ancillary medicine which ought to be in the hands of an organised body of workers. When the movement for the recognition of chiropractic in this manner first took shape many members of the medical profession viewed it with but qualified approval. But with the spread of scientific knowledge a too exclusive attitude has long been found illogical. As medicine in the development of its own work has had to call for aid from other sciences, the necessity for proper co-operation in medical work with workers outside the professional roll became clear and the increasing importance attributed in the medical curriculum to the preliminary subjects may be mentioned in obvious proof. But the spirit thus shown in the scheme of general medical education has not stopped there but has extended to various fields of practice, and the Society of Chiropractors forms a good example of this. When the movement for professional collaboration with the society originated there were found in opposition those who held that the absence of full medical training made professional union a dangerous course, but those who desired to see professional co-operation occur were able to counter by saying that as a matter of fact the fully qualified medical man had not, save in the instance of a few specialists, cultivated that field of therapeutics. The treatment of the foot, apart from definite surgical treatment, had been left to the charge of chiropractors and the advocates of proper collaboration held that it was a duty of the medical profession to assist the chiropractors to become an organised and standardised body, with whom regular medical consultation could take place. The liberal view was taken with the approval of the Royal Colleges and the British Medical Association, and the effect has been successful. The society, in association with its Foot Hospital, is doing valuable work and extending its activities throughout the country.

A PANORAMA OF CURRENT THERAPEUTICS

THIS week the first 35 articles of the series on treatment in general practice now running in the *British Medical Journal* have been issued together in the form of an attractive book.¹ The contributions include those on diseases of the respiratory tract (14), acute specific fevers (6), and cardiovascular diseases (15); the other group of articles published in 1935—referring to the nervous system—and those on the

treatment of digestive disorders appearing this year week by week, with their successors, will be collected in subsequent volumes. The whole will form, as the editor of the *British Medical Journal* says in his preface, a panorama of current therapeutics, a composite picture of the art and science of medicine to-day none the less valuable because parts of it will need touching up and perhaps even repainting to-morrow. All the contributors are teachers of clinical medicine in various schools, and the practical simplicity of the methods of treatment outlined refutes once again the calumny that the outlook of the modern specialist is too academic or his armamentarium too dependent on diagnostic aids to make his advice of much use outside the great cities. At the same time some of the credit for the practical, even occasionally dogmatic, nature of the teaching is due to editorial vigilance. The volume is slender enough to be pleasant to handle and the type is easy to read.

WE regret to learn the sudden death at Farncombe on Sunday last of Sir James Smith Whitaker, late senior medical officer to the Ministry of Health.

Dr. A. Rupert Hallam, lecturer on dermatology in the University of Sheffield, has been appointed by the National Radium Trust to be a member of the Radium Commission, in succession to Sir Arthur Hall.

THE Lister memorial lecture will be delivered by Sir Robert Muir, F.R.S., at the Royal College of Surgeons of England on Tuesday, April 7th, at 5 o'clock. He will speak on malignancy with illustrations from the pathology of the mammal.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Capt. E. MacEwan to *Barham* (on transfer of flag).
Surg. Lt.-Comdr. J. H. Nicolson to *Woolwich*.
Surg. Lt.-Comdr. (D.) L. R. Armstrong to *Pembroke* for R.N.B.
Surg. Lts. J. G. Slimon to *Challenger*; A. H. O'Malley to *Victory* for R.N.B.; and C. J. Mullen to *Pembroke* for R.N.B.
Surg. Lt. (D.) R. S. Jenkins to *Woolwich*.
The following have received appointments as Surg. Lts. for short service: B. M. Goldsworthy, St. Thomas's Hospital; T. J. Harkin, Royal College of Surgeons in Ireland; M. G. H. Heugh, London Hospital; L. Merrill, Guy's Hospital; E. H. Murchison, Glasgow University; and G. A. Maxwell Smith, Edinburgh University.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. S. C. Suggitt to *Pembroke* for R.N.B.

ROYAL ARMY MEDICAL CORPS

Lt.-Cols. E. G. R. Lithgow and P. C. Field retire on ret. pay.
Majs. L. M. Routh and F. D. Annesley, M.C., to be Lt.-Cols.

TERRITORIAL ARMY

Supernumerary for service with O.T.C.—Lt. N. J. Logie (empld. Aberdeen Univ. Contgt. (Med. Unit), Sen. Div., O.T.C.) to be Capt.

ROYAL AIR FORCE

Group Capt. F. N. B. Smartt to Headquarters, R.A.F., Iraq, Hinaidi.

Flying Offrs. A. S. Amsden to No. 3 Armament Training Camp, Sutton Bridge, and H. E. Bellringer to No. 1 Armament Training Camp, Catfoss.

Dental Branch.—Flight Lt. W. D. Guyler to R.A.F. Record Office, Ruislip. Flying Offrs. I. St. C. Alderdice, O. F. Brown, J. H. G. Fensom, S. Hill, R. A. Pepper, and W. A. H. Smith to Medical Training Depot, Halton, on appointment to non-permanent commissions.

PROGNOSIS

A Series of Signed Articles contributed by invitation

XCIV.—PROGNOSIS IN FRACTURES OF THE OS CALCIS

A MAN who fractures his os calcis wants to know first how long it will be before it has recovered, and next, whether there will be any permanent disability. The prognosis in both respects depends primarily on two essential factors: early and accurate diagnosis and efficient treatment. The diagnosis may be obvious, as with a man who lands on his feet from a height and has great pain and broadening of his heel, but in other cases it may be overlooked unless an X ray is taken. Indeed an X ray is essential not only for diagnosis but for determining the exact variety of fracture. An ordinary but true lateral view sufficiently good to show up at least some details of the internal architecture of the bone must be obtained as well as the special oblique posterior-superior view used for os calcis work. It is sometimes only in the latter view that the fracture is recognisable.

The notes and figures on prognosis set out below are based on the patients with fractures of the os calcis treated by the surgical staff at

Type.	Cases.	Weeks of disability	Functional result.
1. Small fracture at anterior end of os calcis.	6	13	G.
2. Fracture of internal tuberosity.	4	10	G.
3. Fracture of upper part of posterior surface (traction type).	5	22	4 G., 1 F.
4. Fracture through the body of the bone, which does not involve the subastragaloid joint.	4	27	G.
5. Fracture involving the subastragaloid joint but with little or no displacement.	13	32	6 G., 6 F., 1 B.
6. Fracture involving the subastragaloid joint with definite displacement.	50	54	21 G., 18 F., 11 B.

G. = good; F. = fair; B. = bad.

St. Bartholomew's Hospital in the last ten years. The records of 82 fractures of this bone occurring in 72 patients have been examined. The fracture was bilateral in 9 patients, one of whom had 3 fractures, the left os calcis being refractured some years later. All were males except 8; the average age was 42. In nearly all cases the injury was caused by the patient falling on his feet from a height, sometimes not great. Most fractures of the os calcis are due to compression of the bone as the patient lands on his heels, but the traction type (vide infra) occurs from the sudden pull of the tendo Achillis as the patient lands on his toes.

It is probably well known that prognosis in fractures of the os calcis is bad; in fact for period of disablement and percentage of subsequent disability it ranks amongst the worst in the body. Although the os calcis is a small bone a number of different types of fracture are recognised, so many, in fact, as to make the nomenclature quite confusing. For the purpose of this article the use of as few subdivisions as possible was contemplated, but six has been found to be the minimal number which suffices (see Table).

As these cases were spread over a period of about ten years several methods of treatment were employed. In many of the earlier cases either no splintage was used or else a wooden back splint for two or three weeks was followed by massage and movements. In later cases the foot was fixed in plaster for from

4 to 6 weeks; and still later for 10 or 12 weeks. More recently in cases where there has been deformity of the bone and the subastragaloid joint has been involved an effort has been made to correct the displacement mechanically by pulling the

posterior part of the bone downwards and backwards by a calliper fixed in the posterior part of the bone and attached to the well-known Böhler's traction apparatus; at the same time the bone has been compressed by a clamp, and the foot then immobilised in plaster. In four cases a subastragaloid arthrodesis had been performed.

As has been indicated above, the patient is concerned with the chances of permanent deformity of the foot and with the economic results likely to ensue. The latter are of the utmost importance to the working man. To estimate the economic results of these fractures we must look not to X rays to see whether perfect anatomical alignment of the fragments has been obtained but to the patient himself to find out whether he has pain or disability, when he was able to return to his previous work, and whether indeed he has not been permanently disabled. Of the 82 cases in this series the present

condition of 52 has been ascertained. The results have been analysed to reveal: (1) the length of time before work could be recommenced; (2) the functional result as regards the foot, which is arbitrarily divided into good (G.), fair (F.), and bad (B.). In the

Table, the average period of disability before work could be recommenced is given in weeks for each type of fracture, followed by a note of the functional result. These results clearly show how closely the prognosis is linked up with the involvement of the subastragaloid joint. Where the joint was not involved good results were obtained, but of the patients in groups 5 and 6, less than half had good functional results and where there was also displacement of fragments a fifth had really bad

FIG. 1.—Types 1, 3, and 4 of fractures of the os calcis are here indicated. The normal "tuberosity-joint angle" formed between two lines, one from the highest point to the anterior angle and the other from the highest point to the upper part of the tuberosity (Böhler), is shown.

FIG. 2.—Type 6, fracture of os calcis showing compression with flattening as indicated by complete loss of "tuberosity-joint angle" so that all three points are in a straight line (cf. Fig. 1). The heel is very short.

results, some being unable to do any work, others being capable only of light work and all having persistent pain. An arthritis in the subastragaloid joint seems to be the cause of the pain; the patient describes it as being on either side of the heel and indicates points where the pain is worst an inch below the malleoli on each side. In the first few weeks after a fall on the heel a patient may complain of severe pain under the heel when he bears any weight on it, but this is relatively transient and the persistent pain is at the sides, more particularly the outer side.

The prognosis thus depends to a great extent on the type of fracture, but there are several other factors which must be taken into consideration. Amongst these are the method of treatment undertaken, the age and weight of the patient, whether he has a tendency to "rheumatism," and last but by no means least his mental outlook. The last is a major consideration in determining recovery after any fracture, and in those, like that of the os calcis cases, which involve a long convalescence it is a most important factor. The patient who has no question of compensation to brood over, has his own business to return to (and the sooner the better for him), who expects and is prepared to put up with some pain and inconvenience, and above all has an optimistic temperament, will recover far quicker than one without such advantages. Often one can judge from the light-hearted and stoical bearing of a patient when first seen that he will return to work as soon as he is allowed, while another in similar plight may drag on gloomily with pain for weeks, perhaps suffering not only from severe pain but also from "compensitis."

Recovery from any fracture is usually slower in the aged than the young, but age is a less important factor in os calcis fractures than is weight. It is hardly to be wondered at, if we consider the position of the os calcis, that the thin short subject makes a quicker recovery than does the heavy one.

Persons prone to "rheumatism" are more likely to get stiffness, pain, and arthritic changes following any injury than are others.

As to the effect of treatment in our series the final result bears no constant relation to the method of treatment employed. Some patients who had but three or four weeks on a back splint had better functional results and less pain than those immobilised for as many weeks in plaster, though mostly the advantage seems to be in the other direction. So many methods are advised for os calcis fractures that it is clear that none is entirely satisfactory; but the one point in treatment that *does* appear to influence the result favourably is a reconstruction of the shape of an os calcis which has been crushed. There are several methods of traction and compression in use for this purpose. But it remains true that two patients with similar fractures and similar treatment may end up with very different functional results.

A prognosis which may seem hopeless, when the os calcis is badly comminuted and deformed and the patient continues to have pain and disability, may be improved if an arthrodesis to fix the joint between the os calcis and astragalus, and perhaps cuboid as well, is performed. Two minor points deserve consideration. In some fractures of the os calcis the bone is not only compressed but is considerably shortened in its antero-posterior length. This diminishes the leverage on which the tendo Achillis works and so gives a certain feeling of weakness to the patient, but should not prevent him from doing his work. In certain very severe cases, where the os calcis is not only greatly comminuted and compressed but the

surrounding bones are also injured, the functional result may be excellent; what really happens is that the os calcis and astragalus unite by bony union, and instead of a painful arthritis the patient has a painless solid joint. It is true that the foot may not be a very good shape, but this is a small price for a working man to pay for freedom from pain.

In conclusion it must be realised when the subastragaloid joint is involved by the fracture there will be little movement in this joint, although the patient may have a good result so far as freedom from pain and ability to work are concerned. The movements of flexion and extension at the ankle-joint are of course unaffected, but inversion and eversion of the foot are very limited and the patient finds difficulty in walking over rough ground or on the side of a hill.

SUMMARY

The prognosis of fractures of the os calcis is considered after a study of the results in a series of 82 cases. The results depend largely on whether the subastragaloid joint is involved. Prognosis also depends to some extent on the age, weight, and mental outlook of the patient and on the method of treatment employed. Those patients with fractures of the os calcis which do not involve the subastragaloid joint may expect to have a foot free from pain and to be able to return to work in three to six months. In those in whom the joint is involved the period of disability is likely to be on an average one year or longer; many of these will have permanent pain and few may expect a good result.

JOHN P. HOSFORD, M.S., F.R.C.S.,
Temporary Assistant Director, Surgical Professorial
Unit, St. Bartholomew's Hospital, London.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
MARCH 14TH, 1936

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2344; diphtheria, 1153; enteric fever, 13; acute pneumonia (primary or influenzal), 1383; puerperal fever, 37; puerperal pyrexia, 117; cerebrospinal fever, 24; acute poliomyelitis, 5; encephalitis lethargica, 6; dysentery, 39; ophthalmia neonatorum, 101. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on March 20th was 5982, which included: Scarlet fever, 664; diphtheria, 1050; measles, 2798; whooping-cough, 712; puerperal fever, 21 mothers (plus 13 babies); encephalitis lethargica, 283; poliomyelitis, 5. At St. Margaret's Hospital there were 21 babies (plus 13 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 106 (39) from measles, 5 (1) from scarlet fever, 33 (5) from whooping-cough, 30 (5) from diphtheria, 57 (17) from diarrhoea and enteritis under two years, and 84 (9) from influenza. The figures in parentheses are those for London itself.

The mortality from measles is still rising, the figures for the last six weeks (working backwards) being 105, 84, 88, 78, 58, 34 for the country as a whole, and 58, 47, 38, 18, 14, 13 for Greater London. Leeds reported 7 deaths, Manchester, Salford, and Shetfield each 4, Liverpool, Wallasey, West Hartlepool each 3, no other great town more than 2. Deaths from influenza are on the wane; this week they are scattered over 46 great towns, Manchester and Birmingham each reporting 5, Shetfield and Leicester each 4, Birmingham reported 5 deaths from whooping-cough. Deaths from diphtheria were reported from 21 great towns, 3 from Manchester. West Hartlepool reported a death from enteric fever.

The number of stillbirths notified during the week was 206 (corresponding to a rate of 39 per 1000 total births), including 37 in London.

SPECIAL ARTICLES

COMPENSATION AND THE RETURN TO WORK

BY JOHN P. STEEL, M.D. Edin.

MEDICAL SUPERINTENDENT, SMITHDOWN ROAD HOSPITAL,
LIVERPOOL

WHEN compensation cases are referred for a definite opinion on the fitness of workmen for resumption of duty, a certain difficulty frequently arises in giving a report. Such cases divide themselves into three categories :

- (a) Those who are fit and those unfit for work.
- (b) Those where there is doubt about the extent of the result of the injury.
- (c) Those suspected of endeavouring to obtain the greatest benefit for themselves as a result of the accident, irrespective of capacity for work.

With those classified under (a) there is no difficulty, and an honest certificate can immediately be given, but those under (b) cannot readily be divided from the cases which are considered in the dubious category of (c). It is not fair to the patient to make a sharp dividing line between the doubtful case and the case considered to be the equivalent of a malingerer, without a very close investigation, not only of the sociological and physical state, but also of the mental attitude of the patient.

When industry is at its height and there is little unemployment, these compensation cases are fairly simple, for the employer is only too pleased to have back a trusted man who is able to do some work for him, and he is willing and able to put profitable work (profitable to both the employer and the employee) into the way of a man who has had, and is returning from, an accident. But when the labour market is overstocked the large employer is able to call on any number of men to do the full work of the injured man at the same rate of wage. The economic factor governing a large business tells the employer to take on a man who can do a full day's work for a full day's pay, and he has to be content, therefore, to have the work done and to pay (or have paid by his insurance company) the man injured in his service at the reasonable rate of compensation laid down by the exigencies of the circumstances. In other words, when the labour market is glutted no employer (or at any rate very few) is able to offer what is commonly known as light work. This lack of "light work" is prone to weigh hardly on the honest employee who has suffered an accident, and has been paid compensation, on behalf of his employer. Let me quote two cases :

(1) A man working at the docks, who had a good reputation with his employers and with his fellow workmen as a man who did all he could for his wages, received a crack fracture of his right tibia when a sack fell from a crane at the side of a ship he was loading. The fracture was treated in the routine way and he had a considerable period off duty, receiving the full amount of compensation he was entitled to. When this had to be reviewed, he was referred for special examination and no gross damage was found.

(2) A man, whose duty it was to climb a ladder of 30 to 50 feet, one day fell, through no fault of his own, and received a somewhat severe jarring, with but little show for his accident. He, in turn, having been injured at work, received the full amount of compensation.

Both of these cases were referred for examination, and in each the same difficulty arose. Whilst no

crippling pathological condition could be found, yet there was a definite feeling that the patient was not able to take up his ordinary avocation. If a certificate had to be given on the present state of the workman, it would have had to be honestly stated that there was no apparent or ascertainable physical disablement, but, nevertheless, it was quite obvious that neither man was able to leave the hospital and start work—full work that is to say—the following morning. Both were more than anxious to get off the compensation period and to earn full wages, for both had dependants relying on them. In neither case, however, did it seem fair to run the risk of putting them at once to the ordinary hazard of their occupation, and a report had to be given saying that they were not fit for their ordinary duties, even though they wished to resume.

One difficulty in these cases is the complete lack of "light work." If a man has had an arm in plaster for seven weeks and has had repeated X rays showing the fracture of a bone and the gradual process of repair, the doctor is not able to take off the plaster and say "that arm is completely healed, there is now no fracture, and work can be started at once." He says "a certain amount of re-education of muscle and nerve is necessary" and recommends the use of the arm and the hand in increasing amount until normality is reached—in other words, a period of re-education. In more prosperous times such a workman who has been under compensation could be referred to light work which acted as re-education, but when the labour market is overstocked this is well-nigh impossible. The referee must then make up his mind whether those in category (b) and (c) are, in the industrial sense, completely recovered or only partially recovered. For the major injury he has to take into account not only the physical disability which has been recovered from, but the psychological trauma. It is not reasonable to expect a man who is a window cleaner by trade to go from hospital (when all his abrasions and bruises are healed and he has had a few days convalescence) back to the work which caused his disability. There is bound to be some psychological shock, and the fear (say) of a repetition of his fall is liable to make his work such that he may fall again.

In cases coming under category (c) the referee cannot say at once, or even after considerable thought, that a man is "swinging the lead," for of all dangerous diagnoses malingering is the one which takes the most substantiating. Where there is any possible doubt—and the case of the workman must be considered as of primary importance for his labour is all he has to sell—a full assessment of physical state, mental ability, and mental retardation or apprehension due to the accident must be made. In these circumstances it does not seem reasonable to ask a physician or a surgeon to give a final report on the desirability of terminating compensation on his own single responsibility.

Where there is the slightest doubt in my mind as to the desirability of re-education I have always endeavoured to have the man retained on compensation for a sufficient length of time for his reference to, and consideration by, a psychiatrist. I feel no loss of dignity in adopting this procedure, for not only is my opinion checked by a man who is a physician, but it is also considered by a practitioner who is able, and has the time, to assess the mental state and outlook of the injured man. I think that, before

the borderline case is put back to hard manual work at which he has suffered an accident and at which he has received psychological trauma, the opinion of an expert in psychological medicine should be obtained. In this way not only will justice be done to the injured man, but an additional safeguard will be offered to the employer against malingering.

The opinion of the physician or surgeon, reinforced by that of the psychiatrist, will carry weight in any court of law. If "light work" is not available it would pay the large insurance companies to have a re-education centre for such cases, for in the good type of workman this re-education is essential before the full day's work can be done for the full day's pay.

THE MATERNITY SERVICES

A Manifesto by the British Medical Association

UNDER the title *An Urgent National Problem* the British Medical Association has issued a reply to recent public statements about maternal mortality in Great Britain. "Maternal mortality," the Association has declared, "is a scientific and administrative problem which deserves careful and scientific study, but, in the experience of practising doctors the publicity which it is receiving to-day is tending to terrify child-bearing women and is, in itself, a cause of increased mortality." In the statement now issued the Association emphasises the fact that maternity is a natural physiological event, though it is one involving complex delicate and important processes. Departures from the normal occur in a small proportion of cases. The vast majority of cases are conducted with complete success in every respect, and, as demonstrated by comparable statistics, there is only one country in the world (Holland) in which safety appears to be *slightly* greater than in this country. In nearly every other country maternal mortality is considerably higher than it is here.

Maternity and its conduct are not concerned merely with attendance during the actual process of delivery but comprise supervision from the time that changes consequent upon conception manifest themselves until the return to normal some short time after childbirth. This whole period cannot be isolated from the rest of the health history and experience of the mother whether before, during, or after the period of actual pregnancy and parturition; it is an integral part of such medical help, advice, and treatment as the mother is accustomed to receive apart from maternity. All available evidence demonstrates that normal confinements, and those which show only minor departures from the normal, can be more safely conducted at home than in hospital.

During recent years a number of authorities have established a type of antenatal clinic in charge of whole-time medical officers; they have provided an increasing number of hospital beds for maternity cases without careful selection of admissions on medical grounds, thus cutting off the local medical practitioners from a considerable part of their maternity experience. This action has been accompanied by an appreciable increase in maternal mortality thereof. The Association points out that where a large number of maternity cases are aggregated in hospitals there is commonly an increased risk of puerperal infection; very disappointingly antenatal clinics, on their present lines, have not been and seem unlikely to be successful. These considerations

are of the first importance when local authorities are considering communal action.

The medical requirements of a woman during the period of maternity are these:

1. Medical supervision *throughout* by the doctor of her choice, with specialist and hospital aids where needed.
2. Efficient nursing and advice by a skilled midwife or maternity nurse of her choice.
3. Provision of help in the house during the period of her actual incapacity.
4. Supply of dressings, special apparatus, or means of transport when required.

There are, of course, large numbers of women who can provide one or more or all of these requirements for themselves, but the Association is strongly of opinion that the State should see to it that, by some means or other, whether by an extension of the scheme of national health insurance or by the action of local health authorities, they should all be available for every mother. There would still remain urgent need for further action to persuade women to take advantage of the means provided for them, for research into the obscure causes of puerperal sepsis and other forms of maternal morbidity, and for the improvement of knowledge, skill, and care among those who have any part to play in the responsibility for the conduct of maternity.

The statement concludes: "Fully appreciative as it is of the great need for improving the position of midwives both as to training, status and finance, the Association believes that legislation to these ends is but a small part of that which is required to remedy the imperfections of the present system, and that it is essential to take steps in rapid succession to establish a complete maternity scheme on the lines indicated in this memorandum, envisaging from the outset the needs of mothers as a whole and the methods of providing for them."

Midwives and Their Views

THE long delay in the appearance of the Midwives Bill after the promise of such a Bill had been made by the Minister of Health was due to the need to consult the local authorities which will have to administer its provisions. The interval has not been lost by organised midwives who have utilised it to find out more exactly what is the position of the midwife in independent practice at the present time. This investigation included the issue of a questionnaire to all midwives believed to be in independent practice through England and Wales, and the abundant information thus accumulated was analysed for the Midwives' Institute by Lady Forber (Dr. Janet Lane Claypon) with the help of Dr. Elizabeth Macrory. Lady Forber used a preliminary analysis of this material in the Fynes-Clinton lecture which was summarised in a leading article in our own columns (1935, ii., 1009). On the eve of publication of the Midwives Bill a considered report of this investigation has now been issued by the Institute in convenient pamphlet form.¹

THE MIDWIFE AS SHE IS

The report is described by Miss E. M. Pye, president of the Institute, as a social document of importance; she emphasises the fact that here is a true picture of the midwife's life as she now lives it. Part I. gives the nearest estimate we have of the number of midwives in practice. Part II. sets out the causes

¹ *The Midwife in Independent Practice To-day*, pp. 32, 6d. (special prices for large quantities), from the Midwives' Institute, 57, Lower Belgrave-street, London, S.W.1.

which have adversely affected this practice. Here it is shown how deeply the increasing hospitalisation of parturient women ("which appears not yet to have reached its maximum") has cut into the midwife's work. The greatest factor in the demand to be delivered in hospital is here found to be the campaign of publicity by which it was expected that maternal mortality would be reduced. The belief has grown up among women that they are less liable in hospital than at home to succumb to the death which they are told may await them as a result of child-bearing; this, it is suggested, carries with it a desire to have a doctor in case anything should go wrong and also probably to avoid pain by having an anaesthetic. Other factors of course are the saving of trouble and often of cost by confinement in hospital and the small space available for the purpose in modern flats. The fees charged by hospitals in many parts are so low that it is cheaper for the mother to go there than to stay at home for her confinement, although the actual cost in hospital must be much higher. In this section of the report the question naturally arises, What is the maternal death-rate in the practice of midwives? When in the past it has been shown that this death-rate is low, the statement has often been countered with the remark that the figures did not include the deaths of women sent in from the midwife's practice to hospital. In the present investigation the cases sent into hospital are included and material is available for releasing the independent midwife from any blame for the alleged high maternal mortality. In this section also is a note on "undercutting and overlapping" in which the great increase of midwives starting practice is attributed to the large number of unnecessary midwives who are being trained. Here it is stated that in a large number of areas the handy-woman is still sufficiently prevalent to be a source of trouble. If the midwife, and the midwife only, was required to notify the birth the presence of a handy-woman conducting the confinement would easily be discovered.

A SALARIED SERVICE

The report also estimates with care the number of midwives who would be needed for the proposed salaried service. Taking 100 births in the year as the number a midwife working whole time may be called upon to attend, it is suggested that just over 2000 midwives would be needed in the large and small towns set out in the Registrar-General's annual summary for 1934. The investigation indicates that the number of practising midwives now over 60 years of age is about 580 and that 1200 others under 60 years of age will not be required. This does not include the rural or smaller urban areas, but in these there are few midwives with large practices, for most of the work is done by nursing associations, the practising midwives only taking relief work for the district nurses. In view of the probability that those displaced will be chiefly the older midwives, the report suggests that a small pension should be the form taken for compensation; women over 50 years of age cannot start a new profession nor as a rule can they take up other work. The scale of pensions and compensation suggested should be studied in comparison with those proposed in the new Bill.

QUESTION OF HIGHER TRAINING

At this opportune time appears also an appeal for the higher training of midwives in a report² by the Council which for 31 years has furthered this object by every possible form of publicity and in so doing

has brought into being the British Hospital for Mothers and Babies at Woolwich from which highly trained midwives have gone out to all parts of this country and the dominions.

"We still greatly hope," the report runs, "that a two years' training may be demanded by Government shortly, for all midwives whether State-registered or not. And as such a course would greatly diminish the numbers of pupils working now in maternity hospitals, we trust that their ranks may be recruited by State-registered nurses receiving a six months' maternity nursing training in contradistinction to midwifery. This course which has been found to answer admirably in Holland has the further inestimable advantage of not interfering with the training of medical students. It is common knowledge that much of the training material, which is so urgently needed for their benefit and that of their future patients, is now absorbed by over 1500 pupil-midwives yearly who have not the faintest intention of using, on behalf of the working mothers or their infants, the experience they have gained."

MIDWIVES AND/OR MATERNITY NURSES

The annual report of the British Hospital, just issued, contains an account of the midwifery service in Holland written by Dr. Eileen Wise, visiting obstetrician, and Miss M. M. Cashmore, sister-matron, who were asked to visit the State training schools for midwives in Amsterdam and Rotterdam. They discovered that trained maternity nurses, as apart from midwives, are an integral part of the Dutch midwifery service and to this fact is due, they think, in great measure the increased maternal safety. In Holland all operative midwifery is referred to well-equipped maternity hospitals, no obstetrician dealing with complicated cases at home. The midwives are State servants with a high status; the competitive entrance examination is only passed by a quarter of the candidates. The theoretical training is directed towards making the midwife capable of thinking. Her clinical training is extensive, simple, and practical, and before its completion she acts as locum tenens for midwives absent from their practices on refresher courses which take place monthly. The larger half of deliveries in Holland are attended by midwives, the remainder by doctors and maternity nurses. The latter are State-registered nurses who, on completion of their general training, have undergone a further six months' training in State maternity hospitals when they are State examined and registered. There is another class of maternity nurse with no general training but with 18 months' training in State maternity schools, and these work among the poor under the district midwives.

ROYAL SUSSEX COUNTY HOSPITAL.—At the annual meeting of the governors on March 11th it was reported that the ordinary income for 1935 fell short of the maintenance expenditure by £8344, and that the deficit had had to be met by drawing upon the limited reserve fund. In spite of the growth of the population of Sussex, and the increased demands made upon the services of the hospital, the income had fallen; and during the year in response to an urgent appeal to provide and maintain at least another 100 beds, less than one-fifth of the money needed had been received. Commenting on the Milk Marketing Board regulations the report states: "It is surely an anomaly that a child in health can be supplied with milk by the education authorities on better terms than hospital authorities can supply milk to that child when sick." The governors regard the increased price of milk as being tantamount to a tax, and it is suggested that the rebate allowed to hospitals on the tax on certain spirits should be regarded as a precedent for granting relief on milk. The milk bill of this large hospital of 272 beds amounted in 1933 (the regulations came into force on Oct. 1st of that year) to £1467. This figure rose to £1588 in 1934 and to £1672 in 1935.

PANEL AND CONTRACT PRACTICE

Prescriptions for which the Insured Person Must Pay

It sometimes happens that insurance practitioners are asked to issue prescriptions for patients who are receiving treatment at hospitals, possibly under arrangements made by the doctors concerned. Here is a case in point where the doctor received a telephone message from the almoner of a hospital asking him to issue a prescription for three Elastoplast bandages for a patient whose treatment at the hospital had involved the use of that number of bandages, the statement being made that unless the doctor would agree to do this the patient would be charged the value of the bandages. The doctor appealed for advice to the insurance committee and was told that an insurance practitioner is called upon to prescribe for insured persons only during the time when he is actively engaged in treating them; his responsibility to prescribe ceases during the time the patient is in receipt of treatment by a member of a hospital medical staff. This point may not appear to be of much moment when the cost involved is but a few shillings, but a rather different complexion is assumed when an appliance such, for example, as a spinal jacket is needed. This particular appliance may now be prescribed by insurance doctors when required for the treatment of fractures, diseases, or dislocations of the spine, and it seems illogical that an insured person should be at the risk of having to pay several pounds for an appliance ordered by a hospital surgeon which if it had been prescribed by his insurance doctor would have been provided free as part of medical benefit. The remedy would perhaps be for the surgeon, to whom the insurance doctor had referred the case, to inform the latter that the patient in his opinion needed the appliance, and for the insurance doctor in his discretion to order it on an insurance prescription. This procedure would follow very closely what happens when a member of a hospital staff advises a particular line of medical treatment, but would of course apply only to those out-patients who had attended the hospital on the advice of the insurance doctor.

Ophthalmic Certificates

Clause 9 (2) of the Terms of Service provides that if the condition of the patient is such as to require any ophthalmic treatment which is not within the scope of the practitioner's obligations the practitioner, if so desired by the patient, shall furnish him with a signed recommendation that such treatment should be obtained. A man recently applied to his approved society for ophthalmic benefit and a letter was issued giving instructions as to procedure. He then went to his doctor and asked for a "written recommendation," but as the doctor considered that his headaches were due to nasal catarrh—there was also slight conjunctivitis—treatment was given for the nasal condition, the doctor indicating that the question of possible ophthalmic treatment could be considered later. The patient did not return for further treatment but in due course the doctor received a letter from the society, reminding him of his obligation, stating that the society had been informed that he had declined to issue a recommendation for ophthalmic benefit as in his opinion glasses were not required, and asking quite nicely for a statement from the doctor as to the circumstances of the case. The doctor informed the society of his opinion, but was rather puzzled as to what obligation, if any, had been

infringed. Clearly none at all, for the clause quoted above refers to the condition of the patient, and the mere fact that an insured person thinks he needs glasses, and obtains a letter from his society, cannot compel the doctor to give a written recommendation against his professional judgment. Societies who find the provision of ophthalmic benefit expensive will doubtless welcome the stand taken by this doctor, but it is rather hard that he should have to go to the trouble of explaining his quite proper action.

Amputation of a Finger

Referees appointed by the Ministry of Health pursuant to Article 43 (4) of the Medical Benefit Consolidated Regulations, 1928, have just issued the report of their inquiry which related to a question whether the amputation of the ring finger of the right hand at the metacarpo-phalangeal joint in the circumstances described is within the range of medical service. The operation in question was performed by Dr. X., an insurance doctor, on April 11th, 1935, in the case of Miss Y., an insured person. Dr. X. practises in Cornwall, but there was not sufficient evidence before the referees of any custom or practice of the medical profession which is peculiar to the area in which this question arose, and accordingly in arriving at their decision they did not have regard to any such custom or practice. The inquiry was held at Truro on Jan. 21st, 1936. At the time of the operation the finger was useless, an X ray examination having disclosed necrosis of the bone. The skin covering the proximal phalanx was healthy. The contentions put forward may be summarised as follows:—

ON BEHALF OF THE INSURANCE COMMITTEE AND THE LOCAL MEDICAL COMMITTEE

(1) That the clinical aspects of the case had to be taken into account.

(2) That though there were no circumstances to add difficulty to the operation as a matter of technique by reason of the state of the hand the line of the incision required to be carefully determined so as to avoid the septic area, lest the sepsis should spread to the hand.

(3) That there was a risk of secondary hæmorrhage and that referees appointed under the medical benefit regulations had held, in the case of the removal of thrombosed and varicose veins in the leg with varicose ulcer, that operation was "attended as it is incidentally by a considerable risk of secondary hæmorrhage" not within the range of medical service.

(4) That therefore the operation in question in the circumstances of this case involved the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess.

ON BEHALF OF THE MINISTER OF HEALTH

(1) That the operation in question did not involve the application of such special skill or experience as aforesaid.

(2) That the difficulty of determining the line of the incision was not such as to demand in the circumstances of this case such special skill or experience as aforesaid.

(3) That the risk of secondary hæmorrhage in the hand was not comparable either in respect of its probability or difficulty of control to that risk in the leg and that therefore the decision of the referees in the case cited on behalf of the insurance committee was not an authority supporting that committee's contention.

Having considered the evidence submitted and the contentions summarised above, the referees accepted those of the Minister of Health and were satisfied that the operation in question did not involve the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess.

CORRESPONDENCE

PROTECTION OF SCIENCE AND LEARNING

To the Editor of THE LANCET

SIR,—The Academic Assistance Council was formed in May, 1933, to assist scholars and scientists who, on grounds of religion, race, or opinion, were unable to continue their work in their own country. Its services have been needed chiefly to help the 1300 university teachers displaced in Germany, but it has also assisted refugee scholars from Russia, Portugal, and other countries.

In coöperation with other organisations, the Council has assisted in permanently re-establishing 363 of the 700 displaced scholars who left Germany. A further 324 are still being temporarily maintained in universities and learned institutions while seeking more permanent positions. The Council has directly received over £46,000 in donations which, with the exception of the small amount used for paying fares of displaced scholars to positions overseas, administrative expenses, and other incidental purposes, have been employed in subsidising research by our refugee guests. The Council, as the international centre for this work, has built up a place-finding organisation and information service which are proving of increasing usefulness.

The Council hoped that its work might be required for only a temporary period, but is now convinced that there is need for a permanent body to assist scholars who are victims of political and religious persecutions. The devastation of the German universities still continues; not only university teachers of Jewish descent, but many others who are regarded as "politically unreliable" are being prevented from making their contribution to the common cause of scholarship.

The Council has decided to establish as its permanent successor a Society for the Protection of Science and Learning, which will continue the Council's various forms of assistance to scholars of any country who, on grounds of religion, race, or opinion, are unable to carry on the scientific work for which they are qualified. One function of the Society will be to build up an academic assistance fund to award research fellowships, tenable in the universities of Great Britain and other countries by the most distinguished of the refugee scholars. This fund will be administered under the auspices of His Grace the Archbishop of Canterbury, the president of the Royal Society, the president of the British Academy, Lord Horder, the Hon. R. H. Brand, and myself.

I appeal confidently and urgently to all those who wish to assist in the defence of free learning and science to join the Society by paying a minimum annual subscription of one guinea. I hope that many will make a larger donation either to the Society or to the fund, or will undertake to covenant with the Society for a seven-year contribution, thus allowing us to recover income-tax on the donations. Gifts to the fund may be earmarked if desired for the establishment of particular fellowships or studentships bearing the name of the donor. This appeal is made with the full coöperation of the organisers of the National Christian Appeal which is about to be made for the destitute non-Jewish refugees from Germany, since the Society will be giving assistance to only one section—namely, the scholars, among the German refugees, irrespective of their religious

affiliations. It is therefore with confidence that I ask support from both the Christian and the Jewish world, and in particular from the university world, to place this most important part of the refugee work on a firm financial basis.

Contributions and subscriptions should be sent to me at the offices of the Academic Assistance Council, 12, Clement's Inn-passage, Clare Market, W.C. 2, made payable to the "Academic Assistance Council."

I am, Sir, yours faithfully,

RUTHERFORD,

President of the Academic Assistance Council.

March, 1936.

THE NUTRITION QUESTION

To the Editor of THE LANCET

SIR,—Dr. Hutchison omits an important point from his quotation from Dr. Friend's "The School-boy." Dr. Friend says that "probably a considerable proportion of the observed increase" (of septic conditions, since 1923) "is due to the fact that about that year the regulations as to sending boys to the infirmary were more strictly enforced, and treatment in the houses was no longer allowed." Dr. Hutchison does not mention Dr. Friend's most striking observation: that the attack-rate of fractures went up in a surprising manner during the period when the boys had vegetable margarine instead of butter, and fell promptly when butter was used again; surely satisfactory evidence of the protective action of this dairy product. Nor does Dr. Hutchison mention that during the period of war shortage, coincidentally with the physical regression, an increasing number of boys showed a disability to cope adequately with the normal school routine; nor the fall in the incidence of acute and subacute rheumatism after the increase of fat in the diet. Surely if Dr. Friend's very qualified evidence about septic conditions is worth quoting, his unqualified evidence on other points is worth quoting also. Strangely enough, Dr. Hutchison also omits the most convincing piece of evidence in support of his thesis—the increased frequency of complications of influenza since the boys have been on a more generous diet.

Dr. Hutchison contradicts himself when he first ascribes lowered resistance to tuberculosis to a deficiency of fat in the diet, and later maintains that there is no proof that dairy products protect us against any of the great killing diseases. The fact that tuberculosis is declining may be evidence that the nutrition of the country is better than it was. But tuberculosis still kills about 30,000 a year; there is still much room for improvement. The death-rate from diabetes is only about one-fifth of this. Even if the increase in the prevalence of diabetes is due to an increase of over-eating, the choice before us is not between under-feeding with the danger of tuberculosis and over-eating with the danger of diabetes. There are such things as common sense and moderation.

It is true that Dr. Spence says that, in his opinion, the main immediate cause of the apparent malnutrition of city children in Newcastle is the physical damage done by infective disease; but he also ascribes the failure of the children to recover equally to housing conditions and inadequate diet. Dr. Hutchison was a member of the committee appointed by the British Medical Association to determine the minimum expenditure on diet compatible with

health and working capacity. As the report of the committee was published without any reservations by Dr. Hutchison it may be assumed that he accepted their conclusions. The Newcastle report, in which Dr. Spence's observations appear, and numerous other surveys show that a considerable proportion of families cannot afford, and actually do not get, diets up to the standard of this committee's minimum. This applies particularly to families with young children.

I am, Sir, yours faithfully,
Bishops Stortford, March 22nd. JOHN MARRACK.

THE ZÜND-BURGUET TREATMENT

To the Editor of THE LANCET

SIR,—My attention has been drawn to Mr. Barwell's assertion in his article on Prognosis in Deafness (THE LANCET, Jan. 25th, p. 214) that the results of the Zünd-Burguet treatment "appear to be evanescent." As one who has had ten years' uninterrupted experience of the electrophonoïde method, I feel it incumbent on me vigorously to deny this aspersion upon what I firmly believe to be a valuable treatment when properly understood and properly applied. A quarter of a century ago, at an annual congress of the Société Française d'Oto-Rhino-Laryngologie, a lively discussion on this subject was closed unanswerably by a member with the words, "My dear colleagues, the outcome of this long discussion is that those who understand the method of Zünd-Burguet are favourable to it, while those who know nothing about it are unfavourable to it." Apparently the situation to-day is exactly similar.

Out of a record of some four hundred cases I would quote the following as examples of permanent improvement:—

(1) A girl of 16, suffering from chronic catarrhal deafness, who in three years has improved for the voice hearing from R. 8", L. 18" to R. 78", L. 240" and is thus able to earn her living as a typist. (2) A lady who, at 21, experienced an attack of unilateral subacute otitis which left her with a reduction of voice hearing in one ear to 24", and a severe, increasing vertigo which incapacitated her for three years. She underwent fifty treatments, with the result that the vertigo disappeared after ten sittings and has never returned, and the hearing became normal. She has remained thus normal for a period of nine years and has become an ardent mountaineer. (3) A lady of 22 with otosclerosis (so diagnosed by several otologists). Treatment in 1925 brought a voice hearing of R. 14", L. 4" after fifty sittings to R. and L. 180". She has kept touch with me and has not gone back. She is now earning her living as a teacher. (4) A lady of 29, also a case of otosclerosis. Whisper hearing in 1932 was R. 10", L. 15". In 1933 it had reached, under the electrophonoïde treatment, R. and L. 240", an improvement which has so far (1936) remained permanent. (5) A lady of 39, who became deaf in one ear from mumps in 1927. I was lucky enough to get her under treatment within a month of its onset. This case was successful and the result has been retained. Details will be found in the *Clinical Journal* for Feb. 8th, 1928.

My results in cases of presbycusis were published in your columns (1934, ii., 306) and speak for themselves. The cases just quoted are but a very small tithe of examples of permanent successes that I have obtained. The two greatest factors in such results are *perseverance* and *coöperation* on the part of both patient and surgeon. Some of my patients have obtained lasting results in a comparatively short time; others have done so only after two years. These essentials do not appear to be appreciated by those who have derided the Zünd-Burguet method. I need hardly mention, in addition, that appropriate

constitutional treatment is a necessary concomitant. This point I have endeavoured to make clear in my "Otosclerosis" (London, 1933).

I am, Sir, yours faithfully,
Harley-street, W., March 19th. MACLEOD YEARSLEY.

PROGNOSIS IN SPINAL CARIES

To the Editor of THE LANCET

SIR,—I am glad to read Sir Henry Gauvain's elucidation of the points I raised. I feel that his letter forms a valuable addendum to what he had already written. At the same time I am sorry to note that the word "discharged" is acquiring a double meaning. I am aware that in the services the letters D.D. are being used to designate fatalities, but in this case the outcome is specified by the qualification discharged dead. It was this word "discharged" that led me astray as I associate this word with the hospital's designation for cases which have left the institution cured, relieved, or incurable. I am correcting the figures in my own copy of THE LANCET to read:—

Period under review September, 1908, to March 31st, 1935—

Cases admitted	1666	
Still under treatment		84
Discharged—		
Cured, relieved, incurable		1521
Died in hospital		61
	1666	1666

I am, Sir, yours faithfully,
Leeds, March 21st. S. D. PERSY FISHER.

GASTRIC ACIDITY AND ITS SIGNIFICANCE

To the Editor of THE LANCET

SIR,—Dr. Hurst's letter in your issue of Jan. 18th interests me much because Dr. Vanzant and I have recently studied the relations between hæmoglobin and gastric acidity in some 3500 persons with hæmoglobin readings ranging from 25 to 130 per cent. and no demonstrable disease in the stomach and duodenum. We have found that, as the hæmoglobin falls off below 75 per cent. mean gastric acidity decreases, and the incidence of achlorhydria rises.

While making this study we found records of dozens of atypical cases in which, in spite of the presence of a marked secondary anaemia, the acidity was higher than normal. On examining these records we found that in most cases the probability was that the patient had an ulcer; the only reason why the diagnosis had not been made was that the roentgenologist had not been able to see a lesion. We then examined dozens of records of patients with marked anaemia due definitely to bleeding from an ulcer and found in almost every case that the acidity was 10 to 15 points above normal, instead of the 20 or 30 points below normal that was to be expected from our experience with persons with severe hypochromic anaemia and no ulcer.

These observations can now be of great help to the physician who cannot find the cause of a severe secondary anaemia. If the gastric acidity is low, he should continue to search for perhaps a carcinoma of the stomach or caecum or for bleeding hæmorrhoids; but if the acidity is abnormally high, and especially if the patient gives a history suggestive of peptic ulcer, the physician can be almost certain that an ulcer is present, even if it cannot be visualised. As

a corollary of this, when a markedly anæmic patient comes with a diagnosis of duodenal ulcer but a low gastric acidity and perhaps few symptoms of ulcer, the clinician will do well to keep searching for the source of the bleeding because it probably is not in the duodenum. Actually, in several cases like this in which the search was continued at the Mayo Clinic, a bleeding lesion was found in the large bowel.

On re-reading Dr. Hurst's letter, one can easily understand now why 17 of his 41 anæmic patients could have a high gastric acidity. Twenty-one were suffering with duodenal ulcer. All of which shows again that when two able observers disagree it is usually because their methods or their material were different or because some unrecognised extra factor was at work.—I am, Sir, yours faithfully,

WALTER C. ALVAREZ.

Mayo Clinic, Rochester, Minnesota, March 10th.

PRURITUS OF THE VULVA AND ANUS .

To the Editor of THE LANCET

SIR,—May I refer to several points raised by your appreciative and critical annotation on the subject of my papers in your issue of March 14th (p. 617). While it is true that the incidence of skin eruptions at any site may "cause" the symptom of pruritus at that site, until the ætiology of the skin eruptions is determined can any claim to have established the "cause" of their symptoms be upheld? The differentiation of the different types of skin eruptions in which irritation of the vulva is a prominent symptom, when the eruption occurs on the vulva, does not solve the ætiology of these eruptions. The ætiology of many eruptions is still unknown. I submit that generally the various types of skin eruptions which occur on the vulva are not differentiated, but that they are merely classified under their most prominent symptom and are called "pruritus vulvæ."

Your annotation expresses surprise at the infrequency of ringworm. Scrapings from suspected cases were in fact negative, and, if results of treatment can be regarded as diagnostic, cure was obtained without the use of fungicides. In regard to the absence from my list of pruritus of "a menopausal or endocrine" origin, does not such a diagnosis involve the assumption that the skin of the vulva is governed by internal factors which have no influence on the skin at any other site? I am unaware of any records of cases of generalised pruritus, or of pruritus at sites remote from the vulva, in which this diagnosis has been definitely established, and in which no skin changes were present. It is a facile diagnosis, acceptable to the patient, since it often confirms her own opinion, and it absolves from further examination of the parts. It is also in harmony with the opinion which is very commonly accepted that the skin of the vulva is a pelvic organ: as the expression goes, "pruritus vulvæ belongs to the gynæcologist." It is for this reason that cases of vulval pruritus are rare in the skin clinics of general hospitals; they are more commonly referred to gynæcological clinics. Few, if any, gynæcologists claim a specialised knowledge of skin affections, and the absence of a differential diagnosis of vulvar skin eruptions is therefore not surprising.

Dr. Agnes Savill's conclusions in your issue of March 21st raise the curious problem as to why fæcal organisms should suddenly become pathogenic to the skin, for even with the most careful hygiene it is inevitable that the parts near the anus should be contaminated by these organisms, from infancy

upwards. Analysis of a large number of urines in my cases yielded such varied results that no definite conclusions could be drawn from them, and irritation appeared to be equally acute in the patient with a neutral sterile urine; with a urine loaded with phosphates; or with a urine in which there was an excess of oxalates, as in the cases in which cultures of *B. coli* were obtained. The analysis and treatment of vaginal discharges do not usually fall within the province of the skin physician, but the results of treatment may, particularly where the patient has some idiosyncrasy.

I have had one case of anal irritation due to worms, but as the eruption did not involve the vulva, this case was not included in the series recorded.

I am, Sir, yours faithfully,

ELIZABETH HUNT.

Manchester-square, London, W., March 23rd.

EPILEPSY AND ALLERGY

To the Editor of THE LANCET

SIR,—The interesting case recorded by Drs. Costello and Fox in your last issue, with reference to an unusual relationship between asthma and epilepsy, raises the question of whether epilepsy can be associated with allergy. I have recently seen in consultation an almost identical case, except that epilepsy was preceded by migraine which invariably culminated after a few hours in either petit or grand mal, on the occurrence of which the migraine ceased. The skin tests to foods, &c., all proved negative. The patient, a woman of 22, had suffered from migraine and epilepsy for many years, and the case may be of interest as affording additional evidence that some cases of epilepsy may be of allergic origin. As far as could be ascertained, there was no family history of allergy. The cyanosis referred to by Drs. Costello and Fox was not, of course, present in a case of migraine, but information as to the mechanisms of the two conditions would be of interest.

I am, Sir, yours faithfully,

Harley-street, W., March 23rd.

G. H. ORIEL.

MORAL PROBLEMS IN HOSPITAL PRACTICE

To the Editor of THE LANCET

SIR,—The American work with this title by Father Patrick A. Finney, C.M., reviewed in your issue of March 14th (p. 640), has already been severely criticised in the October, 1935, number of the *Catholic Medical Guardian*, the organ of the Catholic Doctors' Guild. The "nihil obstat," and other marks of ecclesiastical approval that it bears, certainly imply that the book contains no actually heretical teaching, but they do not guarantee that the author will command universal acceptance by his co-religionists in his application of Catholic principles to medical practice. On one important question Father Finney has failed to distinguish between a decided and binding dogma of the Church and a matter on which opinion is divided—viz., ectopic gestation. Catholic doctors in this country are advised that operation on the unruptured tube is perfectly permissible, since the tube is in a diseased state, and they do in fact carry out the usual procedure in treating this condition.

We entirely concur that "the conduct which is enjoined by Father Finney on hospital sisters" is contrary to the accepted relationship between the medical and nursing professions in this country and places a quite unsuitable responsibility on the nursing sister. Naturally it is assumed that in hospitals conducted under Catholic auspices operations

definitely regarded as unlawful by Catholics, such as direct abortion and sterilisation, cannot be performed, but this does not in our opinion justify turning a nurse into the surgeon's invigilator. It appears, however, that in America the situation is different to anything that prevails in Europe, and there are many Catholic hospitals owned and managed by Catholic religious orders which have no Catholic doctor on the staff and no priest readily available.

Finally we would point out that since Catholics attach much greater importance to the sacrament of baptism than do many others, it is necessary to give particular and detailed instructions to the nurses in the interests of the child. Here again, however, we must admit that Father Finney goes far beyond the common interpretation of medical obligation, and also of medical practice. The "duty" to baptise the unborn child is strictly conditioned by a further obligation not to mishandle the dead mother uselessly or to endanger the living. It is hardly conceivable that nurses should perform post-mortem Cæsarean sections or that they should rupture the membranes in order to baptise an infant only possibly alive! Few Catholic doctors in the course of a long professional life feel called upon to do either of these things.

The Catholic faith is rational and seeks to conserve life, the life of the body and the life of the soul. It is unfortunate if its aims should be misunderstood through an interpretation tinged perhaps with excess of zeal.—I am, Sir, yours faithfully,

ERNEST E. WARE,

March 22nd.

Master of the Catholic Doctors' Guild.

THE FUTURE OF THE CORONER

To the Editor of THE LANCET

SIR,—I have been much interested in the controversy about the coroner system which has been discussed during the past year in your columns and was the subject of a leading article in your issue of Feb. 15th. As a result of similar scandals arising in the coroner system in Suffolk County, Massachusetts, which includes Boston, the coroner system was abolished in this State by legislative act in 1877. The Massachusetts Bar Association and the Massachusetts Medical Society through their joint action brought about this change. They based their criticisms upon the following:

1. The coroner was required to exercise both medical and legal functions, a straddling of two professions, difficult to compass even for an exceptionally brilliant person.

2. The office of coroner, while perhaps necessary under the primitive conditions existing in the early Anglo-Saxon period, had become an anachronism following the development of police and judicial systems.

3. In the investigation of a death by violence two primary questions present themselves: (a) what caused the death? the answer to which can only be supplied by medical investigation; (b) who caused the death? a matter for the police and the courts to determine.

Under the Massachusetts medical examiner system, medical men are called upon to determine the cause and, if possible from the medical facts disclosed, the manner of the death, in cases in which death is supposed to be due to violence. Inquests are limited to cases in which death may have been due to the act or negligence of another, and are held before a judge of a court of first instance, without a jury. If probable cause of action is found the suspect is held for grand jury investigation, and if an indictment is issued the evidence is presented before a superior court with jury. Within the recent period inquests have been sharply limited. Deaths under anaes-

thetics, for example, are not inquested unless there is an indication of criminal negligence. In most other cases the police and the lower courts have already taken cognisance of the matter before the medical investigation has been completed in detail.

The medical examiner system has been subjected to 58 years of trial in this jurisdiction and has been adopted in neighbouring States, in New York City, and in Essex County, New Jersey. As I have suggested, the system makes for simplicity, utility, and efficiency.

I am, Sir, yours faithfully,

TIMOTHY LEARY,

Medical Examiner, Suffolk County, Massachusetts.
Boston, March 10th.

AN ADDRESS IN HARLEY STREET

To the Editor of THE LANCET

SIR,—In your issue of March 14th you published a letter with reference to medical refugees in this country. I have consulted the Jewish authorities interested in the question and find that to the best of their knowledge about 140 German doctors have received permission to practise here, of whom 35 have been permitted to practise in the Harley-street area. This latter group consists of men of specialist rank in their own country. To see these figures in their proper perspective, may I add that there are about 57,000 names on the Medical Register and I believe there are about 40,000 doctors in practice in Great Britain.

I am, Sir, yours faithfully,

March 24th.

SAMSON WRIGHT.

THE RECORD BREAKER

To the Editor of THE LANCET

SIR,—In your account last week (p. 664) of the discussion on Fatigue at the Hunterian Society I am reported as having said that "the record breaker was not usually the educated person." I shall be obliged for the opportunity to correct this misstatement which is likely to call forth a storm of indignant protest; in fact, premonitory rumbles have already reached me. In replying to questions, I had endeavoured to differentiate athletic psychological types, in particular contrasting the highly strung, usually encountered in the devotees of events of speed and those demanding accuracy of technique, with the more stolid unemotional participants in long-distance events and feats of endurance. The great majority of the former belong to what for convenience one terms the educated class; with rare exceptions the latter are manual workers. No mention of "record-breaking" was made: were this under consideration, an analysis would show that the educated and, on occasion, the very highly educated are well represented.

I am, Sir, yours faithfully,

Brook-street, W., March 21st. ADOLPHE ABRAHAMS.

A QUESTION OF PROFESSIONAL CONFIDENCE

To the Editor of THE LANCET

SIR,—The letter of Iatros moves me to send you particulars of another tragedy also revolving round the gonococcus, though in this case I am happy to add that the patient has not suffered.

Dr. A, practising in contract with the X insurance committee, treated his patient Miss N for acute gonococcal vaginitis and endometritis and when she was convalescent sent her into the area of Dr. B, practising in contract

with the Y insurance committee. Before she made the journey to stay with her aunt, who with her husband are valued patients of Dr. B's, Dr. A wrote to Dr. B saying "you will shortly be asked to accept as a temporary resident Miss N" and giving particulars. While Miss N was under his care Dr. B had occasion to inform Dr. A of her progress both by telephone and by letter, eventually returning her to his care with a final letter. Then came the completion of the temporary record form. Dr. B, having some acquaintance with the organisation of the Y insurance committee's office and knowing girls were in employment there, did not feel inclined to make a diagnosis of gonorrhœa which might meet their eye; he further had a delicacy about possible publication within a few miles of the residence of the patient's uncle and aunt of a fact which he had managed to avoid telling them when the patient was actually under treatment in their house—namely, that their unmarried niece had acquired venereal disease. He therefore completed the form so far as was necessary to inform Dr. A of facts not included in the direct correspondence.

The clerk to the Y insurance committee thereupon returned the record form on the ground that it contained insufficient professional details; and also acted in the same way in a similar case. Dr. B saw no reason to alter a form which he had every reason to consider satisfactory to Dr. A; and, since the action of the clerk constituted evidence that his professional statements were scrutinised by a layman, to wit, the clerk, he had every reason to avoid giving details which would constitute a breach of professional confidence. He has therefore in cases where there is reasonable ground to suppose patients would object to disclosure of details treated them without acceptance as temporary residents, to the detriment of his pocket but the integrity of his reputation. He obviously cannot return records which the clerk has already refused to accept and forward; and every reason to decline to amplify them to satisfy the clerk.

Since these occurrences the clerk has included the two temporary record forms in complaints made by him against Dr. B, and at the hearing of the first of these complaints stated that two of the temporary record forms had been returned by him because they were not full enough, and Dr. B had failed to return the same. This statement passed unchallenged by any of the members of the medical service sub-committee which has twice recommended deductions from Dr. B's remuneration for delay in returning medical records of which these are two. Dr. B cannot explain himself to the insurance committee without breaking confidence; and when he challenges the right of the clerk to return records for reasons connected with professional information and comments that another insurance committee known to him make provision for the forwarding of such records from one practitioner to another under cover, the committee reply that they "join issue."

I am, Sir, yours faithfully,

March 21st.

IATROS II.

To the Editor of THE LANCET

SIR,—I was much interested in the letter of "Iatros" last week and in your reply, as I have recently dealt with a similar case. As the letter reads, and with the lack of fuller information, Dr. A was in my opinion absolutely right in the action he took and in giving the information he did to the girl's mistress. Granted that it was not strict etiquette to examine the bed letter, at any rate the girl was Dr. A's patient and the inspection of the letter was made quite openly in the presence of the nurse. Evidently some condition was present quite different from an acute abdomen. In a general hospital, as this obviously was, a girl is not placed in

a V.D. ward without the corroboration and positive evidence which the hospital is capable of obtaining and verifying; we may be sure that the girl was suffering from a gonococcal infection.

For myself I rather blame the physician in charge of the case that he did not advise Dr. A that the girl was not a case of "acute abdomen" for which she had been sent to the hospital. Knowing what Dr. A did (apart from his inspection of the bed letter) was he to allow this girl to return to an unsuspecting mistress who would continue to believe that the girl's past had been a creditable one, to a house where perhaps there were young children, where perhaps she would use the same towels and sleep in the same room with another maid? Which of us would like this to happen in our own house? Knowing the months these cases often take to be cured, is it probable that a general hospital would keep a patient all this time, and what about recrudescence after apparent cure? One is, I am afraid, a trifle suspicious of these girls with a "highly creditable record" and in any case she would not remain innocent long after a stay in the V.D. ward of a general hospital. What alternative had Dr. A, and what would have been his position if as a result of his silence others had become infected? The dismissal was perhaps sent rather crudely and suddenly to a girl with a highly creditable record—hence her hysterical state. It might have been wiser if Dr. A and the mistress had decided to tell the girl that the illness would be a long one and that the mistress could not await her return.

In your note you mention that the condition present might have been confused with other conditions such as effects produced by contraceptive measures. This would not be very creditable to the bacteriological staff of a general hospital, and the fact that she was in a V.D. ward should justify Dr. A in the action he took.

I am, Sir, yours faithfully,

March 22nd.

F.R.C.S.

A DISCLAIMER.—We have received from Dr. Stanley Hartfall and Dr. Hugh Garland a disclaimer of any association with the recent publicity given in the press to the gold treatment of rheumatoid arthritis. The connexion of their names, they state, with the articles in question has been due to the action of a news agency which has circulated paragraphs taken from a short communication by them to the last number of the Leeds Medical Society Magazine.

PARIS

(FROM OUR OWN CORRESPONDENT)

DEATH OF ARNOLD NETTER

AFTER addressing a meeting in Paris on March 1st of the Assemblée française de Médecine Générale, Dr. Arnold Netter died suddenly while the discussion was still in progress. Professor of the faculty of medicine of Paris and honorary physician to the Trousseau Hospital, he had distinguished himself as a pædiatrician and had made valuable studies of broncho-pneumonia, cerebro-spinal meningitis, infantile paralysis, and lethargic encephalitis; his work on the relationship between zona and chicken-pox was also of considerable value. The dramatic circumstances of his death are reminiscent of a scene at the Academy of Sciences, before which Dr. Lucas-Championnière was presenting a report when he collapsed suddenly and died. Dr. Netter was an

octogenarian, but his last discourse, on the fixation abscess with special reference to its use in encephalitis, had won applause for its intrinsic merits as well as in tribute to its author's personality. It may be noted that the opinion of the meeting seemed strongly in favour of the use of fixation abscesses in many forms of illness; though a more critical attitude was maintained in at least one quarter.

CREMATION IN FRANCE

In the March number of *Annales d'hygiène* Dr. Emile Malespine has published a historical survey, conceived in a philosophical spirit, of the disposal of the dead. As he points out, the mode of destruction of a dead body is far less complicated than the psychological and spiritual problems connected with it. "The problem of the cadaver is inseparable from the problem of the cult of the dead, and this cult has its roots in the deepest forces of humanity and the spirit of religion, and it dominates the social life. A nation loses its *raison d'être*, a nation dies if it no longer feels the mysterious threads attaching it to its dead and to the past." It was during the French Revolution that the idea of cremation took concrete form in a project for its realisation, but this project was referred back to a commission in which it was duly buried. It was not till 1874 that cremation was again considered as a practicable solution of the problem of the disposal of the dead. In this year the bodies of three women were cremated in Germany in a Siemens furnace. The idea spread, and soon schemes were afoot for the creation of crematoria in most of the large towns of Europe. In 1889 the crematorium of Père-Lachaise in Paris was inaugurated, and in the same year 49 cremations were effected in this centre. Since then there has, indeed, been a steady rise in the number in Paris, from one decade to another, but the figures certainly do not testify to any great and popular movement in favour of this mode of disposal of the dead. Thus in 1890 there were 121 cremations. In 1900 the number rose to 297, and in 1910 to 473. There were 560 cremations in 1920, 899 in 1930, and 904 in 1934. At the present time cremation is requested in barely 1 per 1000 deaths, and it does not seem as if in France it is likely to make great headway. Why? Dr. Malespine is careful to avoid specific references to the attitude of the Roman Catholic Church to cremation, and he seems more inclined to be philosophically resigned over, than to tilt against, those psychological inhibitions which play so important a part after as well as during life. Respect for the dead cannot be contemptuously dismissed with such a catchword as "fetishism of the cadaver."

CENTENARY OF THE ROYAL MEDICAL BENEVOLENT FUND

THE hundredth annual general meeting of the supporters of the Fund was held in the library of the Medical Society of London on Tuesday last, March 24th, at 5 P.M., Sir THOMAS BARLOW, president of the Fund, presiding. The members stood in silence for a brief space in respectful tribute to his late Majesty, King George V., a patron of the Fund since 1913.

Mr. R. M. HANDFIELD-JONES, hon. secretary, then presented the annual report. He said that the annual meetings were purely formal and designed to meet statutory requirements. But he was able to state that the president had invited the honorary local secretaries to meet at his house to discuss an

appeal to be made in April and sent to everyone on the Medical Register, except where a benevolent fund is already in existence. The meeting at Sir Thomas Barlow's house would discuss how the appeal can be made more powerful. With the same object a conversation will be held shortly, when the Royal Society of Medicine has offered the use of its premises and have asked the members of the Fund to be their guests.

ANNUAL REPORT

He then read the report which showed a story of expansion, very slow at first but substantial of recent years. For example, while in early days the annual subscriptions never exceeded £2250, by the ninetieth year of the Fund the income from this source had risen to £7000 and had reached £14,500 in the centenary year. The committee however had had to expend nearly £700 in annual grants more than was actually received in income during the year, so numerous and urgent had been the appeals. By the jubilee year of the Fund (1886) the Fund had distributed £60,000 among the less fortunate members of the profession; by the centenary year close on £400,000 had been thus expended. The report concluded by stating that a brief historical record of its activities, written by Sir Humphry Rolleston, would be issued in April with the general appeal to practitioners.

Commenting on the report Sir THOMAS BARLOW remarked that he did not know of a charity which displayed more kindness in the way it was administered.

FINANCIAL STATEMENT

Dr. LEWIS G. GLOVER, hon. treasurer, in presenting the accounts, pointed out that from January to December grants are allocated carrying on for the next year, thus committing the Fund to a large expenditure in the immediate future. The Fund was solvent but care had to be exercised over expenditure. The number of grants and annuities had increased by 138 over the previous year; in 1935 there were 240 more beneficiaries than in 1927. The money invested at the moment was £225,000; £2058 had been received through the B.M.A., allocated by subscribers to the Fund. The actual amount of money distributed was £2415 more than was given in the last year, including £865 for Christmas gifts, money resulting from Sir Thomas Barlow's letter in the medical press at Christmas, and from collections at meetings, mostly B.M.A. and panel committees. £1123 were received from the Ladies' Guild as the proceeds of a charity *matinée*, and £207 from the provinces as the result of dinners and dances and social functions held in aid of the Fund. The working expenses were 9 per cent. this year as against 9.3 per cent. last year, and he would point out that societies analogous to their own in calculating percentage of working expenses take into account all money received in legacies, in which case the expenses of the Fund would be only 5 per cent. of the total income received.

Dr. W. P. S. BRANSON expressed the gratitude of the meeting to the honorary officials of the Fund, and Dr. HERBERT SPENCER, who seconded the proposal, said he thought £100,000 would be a good figure to aim at for the centenary appeal.

At the conclusion of the meeting the hon. treasurer announced, relative to the special appeal which is to be issued in April, that Sir Thomas Barlow had headed the list of contributors to the centenary fund by a donation of £1000.

OBITUARY

ALEXANDER ROBERT TWEEDIE, F.R.C.S. Eng.
 AURAL SURGEON, NOTTINGHAM GENERAL HOSPITAL

THE death of Mr. Tweedie, the well-known otologist and laryngologist of Nottingham, occurred suddenly in Nottingham on Wednesday, March 18th.

Alexander Tweedie received his medical education at St. Bartholomew's Hospital, entering the medical school with a scholarship, qualified in 1900 with the English double diplomas, and in the following year obtained the F.R.C.S. Eng. After qualification he did post-graduate work in Vienna and then held a resident appointment at the Royal Free Hospital, but having selected laryngology as a specialty he became clinical assistant to the Hospital for Diseases of the Throat, Golden-square. He then went into practice in Nottingham where he was prompt to make his mark. He was elected assistant surgeon to the Nottingham General Hospital and to the Children's Hospital, and also held the appointment of aural surgeon to the Midland Institution for the Blind. In the South African war he served as civil surgeon in the South African Field Force. On his return to practice he became surgeon to the ear, nose, and throat department of the General Hospital and laryngologist to the Nottingham City Mental Hospital, and soon had a large consulting practice. As the result of these varied experiences he made well-informed communications to the *Journal of Laryngology, Rhinology, and Otology*—to the staff of which journal he was attached—to the *British Medical Journal*, the *British Dental Journal*, *The Lancet*, and the *Journal of the R.A.M.C.*, while in collaboration with Keith he contributed to the *Proceedings* of the Royal Society of Medicine a communication on congenital anomalies of nose, palate, and upper lip. This does not exhaust his communications to the *Proceedings* of this society, while he was a useful contributor to the debates and became president of the otological section. He was a prominent member of the Nottingham Medico-Chirurgical Society and an ex-president of this society. He was a corresponding member of the Austrian Otological Society and the Paris Society of Laryngologists, and treasurer of the Oto-rhino-laryngological Collegium.

Tweedie did fine and varied service during the European war. He personally raised a second line of ambulances and went overseas to be present at the opening of the Gallipoli campaign. He had under his administration a large medical organisation at Alexandria, served in the expedition to Tripoli against the Senuse, and had at one time charge in upper Egypt of a large medical district where he was commanding officer at the Citadel Hospital, Cairo. He was present at the final assault on Gaza as medical officer to one of the divisions, and joined in the pursuit of the Turks to Jaffa and Jerusalem. He was demobilised with the rank of lieutenant-colonel and was mentioned in dispatches. After the war, on his return to Nottingham, he found time in addition to the care of his practice to play an important part in the institutional care of the deaf and of the blind while also acting as local aural specialist to the Ministry of Pensions. In 1920 he was elected to the Nottingham City Council and served on various committees in connexion with health, care of mental deficiency, and management of asylums, but he did not seek re-election at the end of his term.

His death occurred in a dramatic manner. He had been present at a scientific meeting in Nottingham

and had just spoken the closing words of the meeting when he suddenly collapsed and died. He was not known to have been in ill-health.

THOMAS MAJOR TIBBETTS, M.D.,
 D.P.H. Lond.

Dr. T. M. Tibbetts, whose sudden death occurred at the age of 67 on March 13th, was a well-known practitioner in Cradley Heath and the surrounding country. He received his medical training in Birmingham and graduated as M.B. in 1892, taking the D.P.H. of the English Royal Colleges a little later. His whole professional life was passed in the Cradley Heath district where his services to public health were varied and valuable. He was for 40 years M.O.H. to the Quarry Bank U.D.C., and in his reports made outspoken attacks on sanitary defaults of overcrowding and other abuses. He became accepted as a leading authority on these subjects, while on the institution of the National Health Insurance system his activity on behalf of the great movement in the early days was of great local influence. In 1916 he wrote a useful treatise on the "Duties and Perplexities of the Panel Doctor." He treated the subject with breezy cheerfulness and plain good sense, and though not forgetting the duties and obligations of the medical man towards his profession, pointed to the duties, owed by the profession to the State, which by the National Insurance Acts were brought into the form of a contract. Dr. Tibbetts is survived by his wife, a daughter, and three sons, one of whom, Dr. A. Tibbetts, was practising in partnership with him.

SIR KEDARNATH DAS, C.I.E., M.D. Calcutta

Sir Kedarnath Das, whose death is announced from Calcutta, was principal of the Carmichael Medical College, and professor of obstetrics and midwifery there. Born in 1867, he was educated at the Scottish Churches College and Calcutta Medical College, and graduated in 1892. His appointment to the Carmichael College came in 1919 after long service to the Campbell Medical School, and he has for many years been the doyen of the medical profession in Calcutta. To Mr. V. B. Green-Armytage we are indebted for the following appreciation of his former colleague:—

"Kedarnath Das was a man of outstanding ability and striking appearance, standing well over 6 feet in height. Exceedingly well read, his main hobby was his library and the collection of data for his monumental work, 'The Obstetrics Forceps—Its History and Evolution,' which meant 12 years of unremitting patient toil and involved an enormous amount of cross-correspondence between authorities throughout the world; and when it is remembered that this correspondence was done in his own handwriting, working in a climate not conducive to burning the midnight oil, with a fan whirring above, winged insects buzzing around and sweat pouring down his arms, one must but applaud his inspired enthusiasm and admit that he produced the only masterpiece on this subject that has ever been published in the English language.

"Kedarnath Das was India's greatest obstetric guru, and wrote innumerable articles on his own speciality. The honours he received gave pleasure to all because they were well earned by integrity, loyalty, and sheer personal merit. He was much

beloved by all his professional brethren, and as a consultant and administrator, his experience and acumen was of the utmost value. He was particularly proud of the fact that he was the first Goodeve Scholar at the Eden Hospital, and was in close touch with it and its professors throughout his life.

"Whatever he did, he did thoroughly with punctilious care as regards detail and procedure, and I remember when we first opened the DumDum Aerodrome, he was one of the earliest to join, and although well over 60, was one of the first to make a flight over Calcutta, taking intense joy that he was thereby inspiring the youth of Bengal to become air-minded. His house was ever open to all medical men in Calcutta and many a pleasant afternoon I have spent there. Nothing gave him more pleasure than showing you round his library and then taking you to the Carmichael Hospital to demonstrate his unique collection of forceps and appliances which he had procured from all over the world, and which he had presented to the hospital museum."

Sir Kedarnath Das was a foundation fellow of the British College of Obstetricians and Gynæcologists and an honorary fellow of the American Association of Obstetricians. He was knighted in 1932.

WILLIAM HOLLAND WILMER, M.D. Virginia

WE announced last week the death of William Wilmer, the distinguished American ophthalmologist and director of the Wilmer Ophthalmological Institute, Baltimore. His name is well known in this country where certain of his patients enjoyed prominent public positions.

Born in 1863, the son of Richard Wilmer, the bishop of Alabama, he received his medical education at the University of Virginia, graduated in medicine there in 1885, and undertook a long course of post-graduate study in his own country and in England. He contributed to scientific journals articles on various aspects of ophthalmology and also on medical aviation in which he was greatly interested. At the seventeenth annual conference of the Oxford Ophthalmological Congress he delivered a very good address on

DR. WILMER

the results of the operative treatment of glaucoma.

At the outbreak of war Wilmer already held a commission in the medical reserve corps of the U.S. Army. He became appointed commandant of the Medical Research Laboratories (Air Service), Long Island, and at the close of hostilities was in surgical charge of the air service of the U.S.A. Expeditionary Forces. He was awarded for his services the D.S.M. medal in 1919 and was later appointed a Commander of the Legion of Honour. His professional, philanthropic, and social duties in his own country were numberless, and at the time of

his death he was professor of ophthalmology at the Johns Hopkins University and director of the associated Wilmer Ophthalmological Institute. This institute expresses a desire among Wilmer's patients and friends that a wide scope should be given to his activities and that his name should be commemorated in connexion with them. In coöperation with the Rockefeller Foundation and the Commonwealth Fund a sum of nearly four million dollars was raised and the Wilmer Ophthalmological Institute was started providing an opportunity for the study of every phase of ophthalmology. In 1929 General Wilmer was elected president of the Association of Military Surgeons of the United States.

DOROTHY MABEL HANSON, M.B. Liverp.

WE regret to announce the tragic death, on March 21st, of Dr. Dorothy Mabel Hanson, who was killed instantly when her car was crushed between two trams near Westminster Bridge. Dr. Hanson was educated at the Belvedere School, Liverpool, and subsequently studied at the Bergman-Osterberg Physical Training College, Dartford, for at that time she intended to become a teacher of games and gymnastics. After teaching for a year at a school in Southend-on-Sea she went to the Manchester School of Massage to study for the teachers' certificate of the Chartered Society of Massage and Medical Gymnastics. With this qualification she returned to Dartford to teach medical gymnastics, but left again in order to qualify as its medical officer by securing the M.B., B.Ch. degree at the University of Liverpool, her home town. Apart from these years the whole of the rest of her working life was spent in the Dartford College. As lecturer in anatomy and remedial exercises and as resident medical officer she fulfilled two quite distinct functions and therefore had opportunities of coming into perhaps more intimate contact with succeeding generations of students than any other teacher. She was the doyenne of the staff, and for most of those who knew her was so much a part of the College that her sudden and tragic death on March 21st came as a profound shock not only to her present colleagues and pupils, but also to very many others who had passed through the College. She was for many years a member of council and examiner for the Chartered Society, where her specialised knowledge of physical training work and postural problems will be sorely missed. She was only 42 years of age.

ELEANOR HODSON, M.B. Edin.

Dr. Eleanor Hodson, who died on Feb. 26th in Canterbury, had a wide reputation as ophthalmologist and social worker. She was a native of Mickleover, Derbyshire, graduated at the University of Edinburgh as M.B., B.Ch. in 1900, and after serving for a time as house surgeon to the National Eye Hospital, Dublin, went to Calcutta where she practised for some years as a specialist in diseases of the eye. On her return to England she continued to carry on her ophthalmological work, travelled much, and grew interested in many aspects of continental life, while in England she became known as a fine rider to hounds. At the outbreak of war, failing to obtain appointment as a specialist with the British Army, she became attached to the Croix Rouge and during the first period of operations was in charge of various French hospitals. Invalided home in the later phases of the war, she was invited to serve with the R.A.M.C.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Nutrition and National Health

THE DEBATE IN THE LORDS

IN the House of Lords on March 18th the Bishop of WINCHESTER asked H.M. Government if in view of widespread malnutrition and the existence of a large milk surplus they would take steps to extend still further the provision already made to supply liquid milk to school-children and to initiate a scheme on similar lines for expectant and nursing mothers and for children under 5. He took his stand largely on the new standard by which to judge nutrition taken by Sir John Orr in his report entitled "Food, Health and Income." There was, he said, plenty of milk available. He would ask the Government the question which had been recently asked in the *Times*: "Why should not some of the milk now poured into factories be poured down human throats?" Against any additional expenditure which might be entailed they must set the saving there would be in respect of hospitals and medical services. In the long run he believed the nation would save rather than lose.

The Earl of RADNOR asked the Government whether they were proposing to take steps to bring the needs of agriculture and the needs of the nation so far as nutrition was concerned more into line. They knew for certain that it was fresh food that the people needed to bring their nutrition up to standard and it was in this country that fresh food could be produced satisfactorily. There was a very wide gap to-day between the price that the producer got and the price the consumer paid. He did not know whether any Government would ever have the courage to have a searching inquiry into the costs of distribution.

Viscount ASTOR spoke of the report, probably the most important of all, of an international commission of experts which had met in London. Being a report of experts it had been ignored by most people. These international experts were unanimous in saying that there was a real problem of malnutrition and that milk was one of the most important diets that should be dealt with. At the Assembly of the League of Nations last September three days were devoted to the discussion of this subject, after which the Assembly passed unanimously a resolution indicating that there ought to be a comprehensive inquiry into (1) nutrition and public health, (2) the repercussions on agriculture and economics of an improved nutrition policy. As a result of that a committee of which he (Lord Astor) was chairman was set up on which sat medical experts, agriculturists, economists, and others. The committee would present an interim report to the Assembly next September. In their interim report his committee would deal only with the Western World; at some future time they would deal with the Far East, where the problem of malnutrition was far more serious than it was in Europe. They hoped very much that as nutrition improved so cheap foods

(Continued from previous page)

and was appointed anaesthetist and reception officer at Military Hospital No. 1, Canterbury. At the conclusion of hostilities she was decorated by the French Government and continued to take a great interest in the sufferings of the French in the devastated areas. When Canterbury decided to "adopt" the villages of Morval and Lesbœufs Dr. Eleanor Hodson was an energetic worker, while in other philanthropic movements she was a conspicuous figure.

would be allowed to go from countries where they could be produced most cheaply into other countries where from causes of climate or other reasons they could not be produced so cheaply. The price of milk to-day was too high. A great deal could be done to reduce the cost of production. He urged the Government to accept the Bishop of Winchester's proposal. He also hoped that the Government would give a lead in developing a wise nutrition policy.

Lord LUKE said that for the last few months he had had the privilege of serving the Government in their campaign for improving the nutrition of the nation. There had been for several years a Standing Advisory Committee to the Ministry of Health on Nutrition. In 1935 the Government reconstituted the committee with wider terms of reference and Lord Kennet, then Minister of Health, invited him (Lord Luke) to become its chairman. The committee had been asked to find out what food the people of this country were eating and to advise whether it was satisfactory from the health point of view. His committee were fully able to endorse the views now generally held in regard to the consumption of milk. The committee had been able already to produce a report on the nutritive value of milk which had been presented to the Minister of Health and would, he understood, be published very shortly. He hoped that the Government, even if they could not accept the precise terms of the motion, would be able to indicate that they would consider favourably proposals for the increased supply of milk to nursing mothers and children.

THE GOVERNMENT'S REPLY

Viscount GAGE, replying for the Government, said that the problem they had to consider was not whether the people were receiving sufficient food to maintain life, but how far the dietaries of the various classes of the community were adequate to promote and maintain full health. That was a question on which in their present state of knowledge various opinions were no doubt possible. No one would suggest that there was no room for improvement, but they would be viewing this matter in a wholly false light if they did not take into account not merely the high standard of living in this country as compared with other countries, but also the steady improvement which had taken place both in the standards of nutrition and in public health. Some striking figures were given in Sir John Orr's book.

These figures showed the increases in the estimated annual consumption per head of certain foodstuffs and indicated the percentage of consumption in 1934 as compared with the period immediately before the war: Fruit, 188 per cent.; potatoes, 101 per cent.; other vegetables, 164 per cent.; butter, 157 per cent.; eggs, 146 per cent.; cheese, 143 per cent.; meat, 106 per cent.; wheat, 93 per cent.

"It will be seen that, with the exception of wheat, flour and potatoes, there has been a substantial increase in the consumption of most of the principal foods since before the War. The largest increases have been in fruit, fresh vegetables, butter and eggs. In each case the rate of increase has been greater since 1924-28 than in the previous fifteen years.

"These increases in consumption of animal fat, and of fruit and fresh vegetables, are increases in foods of high biological value."

Notwithstanding the industrial depression there had been no halt in the improvement of public health, and for this the health services could claim their share of credit. Of course, it could not be assumed that in all parts of the country and in regard to every class of the community these average figures would apply equally. Nevertheless it could be hardly disputed that the recent social history of this country revealed rising standards of living, improving

standards of nutrition, and better health accompanied by a remarkable increase in the length of life.

USE OF SURPLUS FOODSTUFFS

The problem to which much attention had been given was that of discovering means to make better use of surplus foodstuffs of high nutritional value in the interests both of public health and the agricultural industry. The problem had been termed one of the marriage of health and agriculture. No doubt the increase which they all desired to see in the consumption of these health-giving substances could readily be attained by drastic reductions in price, but a marriage arranged on these terms might well be a marriage of convenience to health, but it would not be particularly welcome to agriculture. But the Government were fully alive to the supreme importance of nutrition to health and had been giving, with the assistance of the Advisory Committee, very close attention to the newly acquired knowledge on the subject. Fortunately, as the Medical Research Council had pointed out, the essential teachings of modern science could be reduced to a few simple statements:—

“On the dietary side, the broad requirements can be simply stated to the public by saying that much more milk (‘safe’ milk), cheese, butter, eggs (especially egg-yolk), and vegetables (especially green vegetables) ought to be consumed. In particular, milk ought to be the chief drink for children, and especially in the first years, while bread and other cereals should in these early years be greatly reduced.”

THE PRESENT CONSUMPTION OF MILK

It was clear, said Lord Gage, that of all food-stuffs milk was from the nutritional point of view by far the most important. Milk was almost a perfect food. Yet the consumption of liquid milk in this country was abnormally low. It averaged about 3 pints per head per week as compared with 5½ in the United States. He thought they might be assured of the value of the schemes already in existence.

Under the milk-in-schools scheme, which covered all children in grant-earning schools and also adolescents attending junior instruction centres aided by the Ministry of Labour, 22,750,000 gallons were consumed during the first year, on which grant amounting to £401,000 was paid. The number of children participating in the scheme had varied monthly between 2,250,000 and nearly 2,900,000. In recent months the number had averaged about 2,600,000. The Milk (Extension of Temporary Provisions) Bill, which had recently passed through Parliament, would enable the milk-in-schools scheme to be continued for a further 12 months until the end of September, 1937. The Education Act, 1921, enabled local education authorities to provide free meals, including milk, for children who needed this help to enable them to take full advantage of the education provided for them. Children obtaining milk in this manner often received two-thirds of a pint or one pint per day. Since that scheme began the number of children in public elementary schools in England and Wales receiving free milk had risen from 100,000 to 275,000. Finally, under the Maternity and Child Welfare Act, 1918, local authorities in England and Wales were empowered to provide free or cheap milk for expectant and nursing mothers and children under 5 years of age. The provision of free milk under these arrangements depended on the recommendation of the medical officer and the inability of the recipient to pay for the milk. Practically all the 422 maternity and child welfare authorities provided some free milk, or at less than cost. About half the milk supplied was in the form of dried milk. Full information as to the annual consumption of milk under maternity and child welfare schemes was not available, but it had been roughly estimated to be equivalent to 7,000,000 gallons—3,500,000 gallons of liquid milk and 5,000,000 lb. of dried milk.

The Ministers of Health and Agriculture had for some time been examining the possibility of a further

extension and encouragement of these milk schemes. The question of consumption was at present under the examination of the Milk Reorganisation Commission, and it would be premature to introduce any new scheme for the provision of milk until the Commission's report had been received.

Workmen's Compensation for Injuries

In the House of Commons on March 20th Mr. MAINWARING moved the second reading of the Employers' Liability Bill. He said that it sought to amend the law in respect of the liability of employers to their workmen for injuries caused to them by the negligence of a fellow workman, and to attach responsibility for such injuries directly to the employer. The Bill was designed to remove an anomaly in the law, the doctrine of common employment, which had been in existence in this country for practically a century. This country alone of the great industrial nations had such a law in operation. An employer was deemed to be responsible for injuries caused in any circumstances by one of his employees to anybody other than his own servants. If an accident resulted in injury to anybody who had common employment in the undertaking then the employer was not responsible.

Mr. A. HENDERSON seconded the motion for the second reading. He said that they were not asking that the workman should be placed in a favoured position, but that he should receive equality of treatment with any other member of the community who was injured as the result of the negligence of another person.

Sir J. WARDLAW MILNE moved the rejection of the Bill. He said that insurance against an indefinite risk of this kind would have to be effected at a high rate. If the Bill became law the temptation to try to prove negligence on the part of a fellow workman would be irresistible, and whereas now much of the compensation paid out was paid without recourse to the Courts, in future there might be protracted cases in the High Court and that would not be for the benefit of the workmen of this country.

Sir D. SOMERVELL, Attorney General, said that the doctrine of common employment was part of the common law of the country. The Bill proposed to alter part of that law. The important point in considering this Bill was that Parliament had affirmed the principle that compensation should be awarded irrespective of negligence. The Bill sought to make the measure of compensation dependent on the proof of negligence. Even assuming that industry could bear this change without detriment to itself, this was, on the whole, a bad use for the money. The effect of the Bill would be in many cases to put a working man in the difficult position of having to make up his mind whether he would risk an action for negligence.

The Bill was rejected by 146 votes to 85.

Midwives Bill

In the House of Commons on March 18th Sir KINGSLEY WOOD, Minister of Health, introduced the Midwives Bill, which was read a first time. An explanatory and financial memorandum, which is prefaced to the Bill, states that the main purpose of the measure is to improve the standard of domiciliary midwifery in England and Wales by establishing an adequate service of salaried midwives. Certain local authorities already exercise to some extent their powers in regard to midwifery under the Maternity and Child Welfare Act, 1918, either by subsidising the midwifery work of local nursing associations or by themselves employing midwives. The present Bill places an obligation on each local supervising authority to secure an adequate service within its area, provides for an Exchequer grant towards the cost of the new service, and deals with other related matters.

Under *Clause 1* it will be the duty of every local supervising authority to secure, whether by making arrange-

ments with welfare councils or voluntary organisations for the employment of midwives as whole-time servants or by itself employing midwives, that an adequate number of salaried midwives is available in its area to attend on women in their own homes as midwives or maternity nurses: the clause provides for the submission to the Minister of proposals for carrying out this duty after consultation with the local bodies concerned.

Clause 2 provides for the advertisement by each authority of the terms of employment in the new service, which is to be on a whole-time basis, and for certain superannuation matters in relation to midwives so employed.

Under *Clause 3* of the Bill authorities will be required to fix scales of fees for the services of their midwives, when acting as such or as maternity nurses, and to recover in each case the appropriate fee, or, if the financial circumstances of the patient do not permit of the payment of the whole charge, such part, if any, as she or the person legally liable to maintain her can afford.

Clause 4 sets out the provisions governing the grants which it is proposed shall be made by the Exchequer towards the cost of the new service. The grants will range from about 85 per cent. of the additional expenditure in the case of the poorest areas to about 20 per cent. in the case of the richest areas, and will amount in all to about half the cost in each year of the new service.

Clause 5 of the Bill provides that a midwife who is not appointed by an authority as a salaried midwife and who agrees to cease practice and to surrender her certificate shall receive compensation based on her emoluments for the last three years, and that any midwife who is required to surrender her certificate by reason of age or infirmity shall receive compensation based on her emoluments for the last five years.

The remaining clauses contain provisions for preventing unqualified persons from practising as nurses in maternity cases, for securing the periodical attendance of certified midwives at courses of instruction to be provided by authorities, and for enabling authorities to defray certain expenses incurred by them under previous Midwives Acts.

In the House of Lords on Tuesday, March 24th, Viscount GAGE introduced a Bill to consolidate and amend certain enactments relating to public health. The Bill was read a first time.

HOUSE OF COMMONS

WEDNESDAY, MARCH 18TH

Quality of Margarine Supplied in Royal Air Force

Mr. LEACH asked the Under-Secretary of State for Air if the low-priced and inferior quality of margarine supplied to the Air Force was of the type to which vitamins A and D had been artificially added or was it of the non-vitamin containing variety.—Sir P. SASSOON replied: The margarine supplied to apprentices and boys in the Royal Air Force is vitaminised, but not that supplied to airmen.

Mr. LEACH: Can the right hon. gentleman say whether the insertion of these vitamins in margarine can actually be performed with success; and does he know that butter contains both these vitamins?

Sir P. SASSOON: I believe medical authorities consider that vitaminised margarine is equal if not superior to butter because the vitamin content of butter varies according to the seasons of the year.

Gastric Disorders Among Omnibus Men

Mr. SHORT asked the Lord President of the Council if he would say what progress the Industrial Health Research Board of the Medical Research Council had made respecting the investigation of the cause of gastric disorders among omnibus men.—Capt. MARGESSON (Parliamentary Secretary to the Treasury) replied: I am informed that the investigation is being actively pursued, but that it has only recently begun and is still in an early stage. It will necessarily take some time to collect reliable statistics to show whether an excessive incidence of gastric

disease is, in fact, associated with this occupation. If an affirmative answer is obtained it is proposed to extend the inquiry to a study of possible causes.

Temperature and Humidity Conditions in Hospitals and Schools

Mr. MARKHAM asked the Minister of Health whether any inquiry was proceeding in this country at the moment into the question of temperature and humidity conditions in schools, hospitals, &c.; and, if not, whether he would take steps to institute such inquiries.—Sir KINGSLEY WOOD replied: I understand that inquiries relating to questions of warmth and comfort in buildings are being carried out by an inter-departmental committee of the Medical Research Council and the Department of Scientific and Industrial Research, and that a further report will shortly be issued by the Council. In these circumstances I do not at present think it necessary to institute further inquiries with special reference to schools or hospitals.

THURSDAY, MARCH 19TH

Medical Treatment in Training Centres

Miss WARD asked the Minister of Labour if he could yet inform the House what steps he proposed to take to provide medical treatment for young men.—Lieut.-Colonel MUIRHEAD (Parliamentary Secretary to the Ministry of Labour) replied: Arrangements are being made to provide treatment in appropriate cases for young men in the special areas of the ages of 18-24 inclusive who are willing to attend a training centre, but who are at the moment prevented from doing so by reason of remediable defects.

Miss WARD: Can my hon. friend say what the arrangements are?

Lieut.-Colonel MUIRHEAD: The arrangements are being undertaken, but they are not yet completed. I cannot give any date for their completion, but they are being pressed on as quickly as possible.

Instruction on the Dangers of Alcohol

Mr. PALING asked the President of the Board of Education whether any steps had been taken by the Board to carry out the recommendation of the Royal Commission on Licensing, paragraph 699, that His Majesty's inspectors should inquire as to the extent to which instruction on the dangers of alcohol was carried out in the schools they visited; and if he could present any return or report showing the results of the inquiries made.—Mr. OLIVER STANLEY replied: The Board's "Handbook of Suggestions on Health Education" contains a chapter on the hygiene of food and drink, which was revised after the publication of the report of the Royal Commission on Licensing, and the Board consider that a knowledge of its contents should be regarded as part of the necessary equipment of every teacher. H.M. inspectors have been instructed to pay particular attention to, and to report on, the health instruction given in schools, but I am unable to furnish a report such as the hon. Member desires.

Special Schools for Mentally Defective Children

Sir FRANCIS FREMANTLE asked the President of the Board of Education if he would say for how many children accommodation was available in special schools for mentally defective children; and for how many accommodation was available 25 years ago.—Mr. OLIVER STANLEY replied: There is accommodation available in special schools for 16,562 mentally defective children as compared with accommodation available in 1911 for 11,854.

Sir F. FREMANTLE: Does the right hon. gentleman think that is satisfactory progress considering the importance of the problem?

Mr. OLIVER STANLEY: In a recent circular I issued I pointed out that there was a need for better residential accommodation for these children in certain areas, and I urged local authorities to make progress in the matter.

Sir FRANCIS FREMANTLE asked the President of the Board of Education if he would arrange for the notification of defective children on leaving school to the mental deficiency authority.—Mr. OLIVER STANLEY replied: Provision is made in Article 4 of the Mental Deficiency

(Notification of Children) Regulations for the notification of mentally defective children due to leave special schools on or before attaining the age of 16. There is no power whereby local education authorities can notify children leaving other schools, but the Board have suggested that such children could be informally brought to the notice of the mental deficiency authorities for friendly supervision on a voluntary basis.

Sir F. FREMANTLE: Is the right hon. gentleman looking after this to see if it is carried out properly because the information generally is that it is not carried out?

Mr. OLIVER STANLEY: The whole question of closer co-operation is now under consideration by the local authorities.

Small Traders and National Health Insurance

Mr. ARTHUR HENDERSON asked the Minister of Health whether he proposed to introduce legislation to allow shopkeepers to become voluntary contributors under the National Health Insurance Acts for the purpose of qualifying for the receipt of benefits, including medical, sickness, and disablement benefits.—Sir KINGSLEY WOOD replied: The answer is in the negative. The new scheme which the Government has announced its intention of introducing will be limited to pensions insurance. The Government feel that the success of the new scheme would be jeopardised by the inclusion of health insurance, because the contribution required to provide the combined benefits would be so substantial as to make the scheme unacceptable to many persons who are anxious to secure the pensions benefits. I would remind the hon. Member that under the National Insurance Act, 1911, shopkeepers and other persons working on their own account had the opportunity of becoming voluntary contributors for health insurance purposes, but the option was withdrawn by the Act of 1918 because of the meagre response to the offer.

Spahlinger Treatment for Tuberculosis

Sir FRANCIS FREMANTLE asked the Minister of Agriculture if adequate experiments were being made in this country to check those in Northern Ireland on the Spahlinger vaccine for the prevention of tuberculosis in cattle; how long these experiments would take; and whether, if it be proved successful, he would take steps to secure its general adoption.—Mr. ELLIOT replied: I am in close touch with the work that has been and is being carried out in Northern Ireland in connexion with the Spahlinger vaccine. The question of conducting tests with the vaccine in this country is under consideration. I am, however, not yet in a position to make a statement as to the scope or duration of any experimental work which may be undertaken.

MONDAY, MARCH 23RD

Small-pox in India

Mr. LEACH asked the Under-Secretary of State for India whether he had received any information with regard to small-pox outbreaks in India; and whether the outbreaks this year had been heavier than usual at this period.—Mr. BUTLER replied: There has recently been an acute epidemic of small-pox in Bengal. Complete up-to-date figures for the Province as a whole are not yet available, but in Calcutta 1558 deaths from small-pox have occurred this year up to March 7th. This is greater than the average of recent years, but the disease comes in waves at irregular intervals.

TUESDAY, MARCH 24TH

Cerebro-spinal Fever in Army Camps

Mr. DAY asked the Secretary of State for War to state the number of cases of cerebro-spinal fever reported and admitted to hospital at Aldershot and/or Catterick during the previous 12 months; and whether there had been any reports from other camps in Great Britain.—Mr. DUFF COOPER replied: The number of cases of cerebro-spinal fever for 1935 were: Aldershot, 7; Catterick, 2. In addition there were 14 cases from various stations throughout Great Britain, making a total of 23. The number of cases from Jan. 1st, 1936, to date are: Aldershot, 1;

Catterick, 4. In addition there were 7 cases at Woolwich, 2 at Chatham, and 1 at Windsor, making a total of 15.

Puerperal Fever in Derbyshire

Mr. HOLLAND asked the Minister of Health how many cases of puerperal fever had occurred in Derbyshire during the past three months; how many of such cases originated in maternity institutions; whether the source of the infection had been traced; and with what results.—Mr. SHAKESPEARE (Parliamentary Secretary to the Ministry of Health) replied: Thirteen cases of puerperal fever were notified in Derbyshire during the 13 weeks ended March 14th. One case occurred in one of the maternity institutions which are provided or subsidised by local authorities and which are, therefore, required to report to my right hon. friend. There were also 11 cases of the condition known as puerperal pyrexia in the same institution during that period. Investigation showed that the source of infection could probably be traced to a throat infection in a member of the staff, and the institution was temporarily closed and the premises disinfected.

MEDICAL SICKNESS, ANNUITY AND LIFE ASSURANCE SOCIETY

The annual report announces that 1936 is a bonus year for members of this society, which is the only insurance company paying a reversionary bonus on its sickness and accident policies as well as on its life policies. The surplus available for distribution depends on the profits of the sickness fund and therefore varies according to the society's experience; in 1932, for example, the bonus was 12s. for each guinea per week insured on each premium paid in the preceding five years, while in 1927 the figure was 15s. per guinea. The directors take an optimistic view of the prospects for 1936, as the present experience seems to be favourable. Prospective members of the society are advised that it is open only to the medical and dental professions; that it is conducted on a "mutual profit" basis; that, if desired, combined policies are issued embodying both life and sickness assurance; that loans for the purchase of practices and house property are offered; and that pension policies are available for insurance practitioners and members of the British Medical Association. In presenting the report of the 51st year of the society the directors speak of continued expansion. The total funds have increased by £147,526 to £1,239,639. The premium income of the life assurance fund amounted to £101,268, and the rate of interest earned on this fund was £4 6s. 3d. per cent. after deduction of tax. The new annual premiums again reached a record figure, amounting to £10,071; the payments for sickness claims increased slightly to £53,494. The total premium income increased to £202,460, and the expenses of administration were reduced by 1.8 per cent. of last year's figures to £19,685; this is 9.7 per cent. of the total premium income. The growth of the society in the last few years has made it necessary to secure larger offices; fortunately it was possible to find the accommodation in the same building in which the society has had its offices since 1914, at 300, High Holborn, London, W.C.1.

RHEUMATIC CLINIC FOR ABERDEEN.—The provision of a clinic for the treatment of rheumatic diseases at Aberdeen is being considered. It is thought the Royal Infirmary buildings at Woolmanhill which will shortly become vacant might be reconstructed for this purpose.

CARDIFF ROYAL INFIRMARY.—There has been a gradual increase in expenditure at this hospital amounting to between £4000 and £5000 a year, and as there is no prospect of reduction, a regular additional income of £5000 a year must be obtained. The chairman of the finance committee has suggested that the weekly contributions from workmen should be raised from 2d. to 3d. a week.

MEDICAL NEWS

University of Oxford

On May 5th in convocation it will be proposed to confer the honorary degree of D.Sc. on Sir Cuthbert Wallace, P.R.C.S., Sir Walter Langdon-Brown, Dr. Robert Hutchison, Prof. Charles Singer, Sir Henry Dale, F.R.S., and Sir George Newman. The degrees will probably be conferred when the British Medical Association meets at Oxford this summer.

A Radcliffe travelling fellowship has been awarded to Dr. A. P. Meiklejohn, Robinson senior scholar of Oriol College.

University of Liverpool

At recent examinations the following candidates were successful:—

Part I.—J. D. Bryan, W. N. M. Mason, T. H. Pierce, F. Pygott, H. R. Shone, Edna L. Smart, B. A. Taylor, Mary M. Thomson, and T. P. Twomey.

D.P.H.
W. Barnetson, A. Boules, D. L. Cran, N. G. Gandhi, R. G. Ghoshal, A. G. Hiremth, M. T. Ismail, B. B. Mukerjee, W. Murray, M. S. Rao, and J. G. Silmon.

D.T.H.
W. Crawford, K. O'Toole, S. K. Ting, and T. P. Tu.
Dr. R. G. Ghoshal has been recommended for the Milne medal.

University of Leeds

Mr. J. C. Gillies has been appointed honorary demonstrator in anatomy, and Mr. D. J. Cork lecturer in dental pathology and bacteriology.

At recent examinations the following candidates were successful:—

M.D.
Bessie Brown and W. H. Tod.
CH.M.
P. R. Allison.

FINAL EXAMINATION FOR M.B., CH.B.

Part I.—N. Baster, Joan M. Bateson, G. R. Bedford, Rosemarie Blackwood, H. Cohen, A. A. Driver, R. W. Ellis, K. M. Fox, V. P. Geoghegan, I. R. Gray, G. W. Green, G. W. V. Greig, T. Hardy, Gwyneth M. Hosking, S. Lask, R. F. Lawrence, S. Levy, N. Livingstone, Agnes M. Mitchell, R. B. Raj, F. P. Raper, J. A. Rhind, A. H. Rhodes, Joyce M. Rhodes, Phyllis M. Richards, I. D. Riley, G. B. Robinson, H. Silverman, C. L. Summerfield, J. C. T. Sykes, D. Taverner, H. Thistlethwaite, L. G. Topham, Mary Townsend, Lella M. Wainman, J. W. Walker, F. J. D. Webster, and F. W. Wigglesworth.

Part II.—G. N. Blackburn, Olive M. Callow, Marie H. Calverley, G. Clarke, J. C. Coates, W. Davidson, W. G. France, W. Hobson, J. Holden, R. L. Lamming, D. M. Leiberman, S. Mattison, W. S. A. Oakes, G. Quayle, O. Scarborough, J. P. Senior, Winnie Shaw, C. E. Stuart, E. H. Tomlin, C. W. Ward, and H. L. L. Wilson.

Part III.—R. L. Lamming (with first class honours); J. C. Coates and W. Hobson (with second class honours); G. N. Blackburn, Olive M. Callow, Marie H. Calverley, G. Clarke, W. Davidson, W. G. France, J. Holden, D. M. Leiberman, S. Mattison, W. S. A. Oakes, G. Quayle, O. Scarborough, Winnie Shaw, C. E. Stuart, E. H. Tomlin, C. W. Ward, and H. L. L. Wilson.

FINAL EXAMINATION FOR L.D.S.

H. C. Brewerton, O. B. Clarke, T. W. Frost, and W. Pickup.
D.P.M.
A. D. D. Broughton and E. Smith.
D.P.H.
J. C. G. Anderton, E. L. Brittain, and J. W. Whitworth.

University of Manchester

Mr. John Morley, lecturer in systematic surgery in the University, has been appointed to the chair of surgery in succession to Prof. E. D. Telford who will retire in June.

Mr. Morley, on leaving Bishop Stortford College, entered the University of Manchester and graduated M.B. with first-class honours in 1908. He obtained the degree of Ch.M. in 1911 and became F.R.C.S. Eng. in the same year. During his course he gained many awards, including the graduate scholarship in medicine, the Bradley scholarship in clinical surgery, the Tom Jones exhibition in anatomy and the Tom Jones surgical scholarship, and the Ashby research scholarship in the diseases of children. He held a demonstratorship in anatomy in the University from 1910 to 1911 and was lecturer in clinical anatomy from 1912 to 1920 when he was appointed a lecturer in applied anatomy. This appointment continued until, in 1930, he took up his present position. During the war he held the rank of captain in the R.A.M.C. (T.F.), and was awarded the Croix de Chevalier of the Legion of Honour for services in Gallipoli. Mr. Morley is consulting surgeon to Ancoats Hospital, assistant surgeon to the Manchester Royal Infirmary, and a consulting surgeon for children to St. Mary's Hospitals, Manchester. His best known work is his book on "Abdominal Pain," published in 1931.

University of Sheffield

At recent examinations the following candidates were successful:—

P. B. L. Potter. *M.D.*

FINAL EXAMINATION FOR M.B., CH.B.

Parts II. and III.—R. T. Gaunt, J. R. Grimoldby (with second class honours); E. D. Belbin, H. A. Cole, J. L. Dales, P. M. Iman, S. Miles, E. L. M. Millar, and Cyril South.

Scholarships for Sons of Medical Men

Sir Milsom Rees scholarships of £100 each to Port Regis Preparatory School, Broadstairs, have been awarded to E. H. B. Smith, son of Major E. C. A. Smith, I.M.S., and to J. M. H. Dickson, son of Dr. W. S. Dickson.

Medical Art Society

The second exhibition of this society, which was founded last year, will be held in July. It is proposed that the members dine together before visiting the exhibition. A certain number of frames of stock sizes will be available for the exhibits of country members. Further information may be had from the hon. secretary, Prof. C. A. Pannett, St. Mary's Hospital, London, W.2. The president is Sir Leonard Hill, F.R.S.

General Medical Council

At the meeting of the executive committee held on Feb. 24th it was announced that the following names erased from the Medical Register under Section 14 of the Medical Act, 1858, had now been restored:

Bennett, Thomas	Kinnear, Joseph
Browne, Patrick F.	Mackenzie, Andrew H.
Fraser, Patrick	Murphy, John K.
Horsley, Lancelot	O'Brien, Catherine M.
Jones, Lewis	Weston, Alfred W.

A reported amendment of the 1928 Act in the Union of South Africa enables holders of New Zealand medical degrees to be registered in the Union, and revokes the right of holders of the M.D. of Royal Universities of Italy. A new regulation by the Saudi Government forbids any doctor, dentist, veterinary surgeon, dental operator, or accoucheuse to practise in the Kingdom of Saudi unless registered under specific conditions by the public health department.

National Ophthalmic Treatment Board

This board has completed a film called "Do You See?" which illustrates in story form the need of watchfulness against eyestrain, and emphasises the danger of receiving eye treatment from anyone but a qualified eye specialist. One sequence of the film deals with the history of spectacles and another shows the activities of the National Eye Service centres which the Board has established in cooperation with the British Medical Association. These centres provide for examination of the eyes of persons of limited means by medical eye specialists at a nominal fee. The address of the Board is 1, High-street, Marylebone, W.1.

The Grenfell Association

Dr. H. L. Paddon gave an address, entitled Twenty-one Years with Sir Wilfrid Grenfell in Labrador, at a meeting on March 18th of the Grenfell Association of Great Britain and Ireland, at which Lord Horder presided. He said that Grenfell found pathetic relics of two races, Eskimos and Indians, which were suffering grievously from contact with white men. He described the havoc played by epidemics of small-pox, influenza, scarlet fever, and measles. The tragedy of the native races could not be stayed, but there still remained the white settlers and mixed stock, and Labrador could be made an industrial asset of the Empire, though the country's resources were still undeveloped. Tuberculosis and nutritional disease were disappearing in the districts round the hospitals and medical centres. Lord Horder said there was no form of human activity for which he would like to appeal more strongly than for the Grenfell Association. Mr. Vincent Massey, High Commissioner for Canada, ascribed to Grenfell the honour of having removed the reproach often applied to Labrador "The land that God gave Cain."

Grading of Milk

Sir Kingsley Wood, the Minister of Health, having considered representations made to him upon the Draft Milk (Special Designations) Order, 1936, has decided to make some modifications in the Order and to postpone the date of operation till June 1st.

Laryngo-phoniatry

Ten lectures on this subject will be given from May 11th to 16th at the Hôpital Bellan, 7, rue du Texel, Paris XIV. Further information may be had from Dr. Jean Tarneaud, 27, Avenue de la Grande Armée, Paris XVI.

London Hospital

Sir William Goschen, chairman of this hospital, announces that of the £80,000 required for extensions only £13,674 has so far been subscribed. It is becoming increasingly difficult to carry on the work of the institution, and as a result of lean and difficult years in the past the loan account stands at £81,000.

Royal Waterloo Hospital, London

This hospital's income last year rose from £24,005 to £24,997, but the weekly cost of each in-patient also rose, from £3 8s. 3½d. to £3 10s. 10½d. The out-patient department is very much congested and it has become necessary to extend the building.

Westminster Hospital

At the end of 1935 over £178,000 had been given or promised to the rebuilding fund of this hospital, and during the last three months promises of sums amounting to a further £12,500 have been received. The sum of £25,000 is needed before the new medical school building, which is badly needed, can be completed.

Clinic for Endocrine Disorders

A new out-patient department for the treatment of endocrine disorders is to be opened at Guy's Hospital, London. It will be regarded purely as a reference department, and for the present there will be only one session weekly. Dr. P. M. F. Bishop, as honorary clinical endocrinologist, will be in charge of the clinic.

Harvey's Statue at Folkestone

On Wednesday next, being the anniversary of his birth in Folkestone, the statue of William Harvey on the Leas will be unveiled in a form more worthy of his birth-place. The statue, 30 ft. in height, cast in bronze, on a granite plinth and pedestal, has been decolorised since its erection in 1881 by the salt air to a mottled green. The inscription on the base, which has long been hardly discernible, is being renovated for all who will to read:—

WILLIAM HARVEY.

The Discoverer of the Circulation of the Blood.

Born in Folkestone April 1, 1578.

Died in London June 3, 1657.

Buried at Hempstead, Essex.

Harvey's memory is also recalled in Folkestone by the stained-glass window in the parish church, and by the grammar school founded by one of his relations.

Congress on Hepatic Insufficiency

An International Congress on Hepatic Insufficiency will be held at Vichy from Sept. 16th to 18th immediately after the International Congress on Gastroenterology which is taking place in Paris from Sept. 13th to 15th. The congress at Vichy will meet under the presidency of Prof. Maurice Loeper (Paris), and the subjects for discussion have been arranged in two sections. Prof. Noel Fiessinger (Paris) will preside over the medicine and biology section, and among those who will contribute to the discussions are Dr. R. Debré, Dr. Gilbrin, Dr. Seme-laigne, Prof. Binet, and Prof. Lemaire (Paris), Dr. Olmer (Marseilles), Dr. Erich Urbach (Vienna), Dr. A. Parhon (Bucharest), and Dr. Hamilton Fairley (London). Prof. Mauriac (Bordeaux) is to preside over the therapy section, and the speakers will include Prof. Brulé, Prof. M. Villaret, Prof. L. Justin-Besançon, Dr. R. Cachera, and Dr. R. Fauvert (Paris), Prof. Piery and Dr. Milhaud (Lyons), Dr. De Grailly (Bordeaux), Dr. F. Gallart-Mones (Barcelona), Prof. B. Pribram (Berlin), Prof. P. Duval, Dr. J. C. Roux, and Dr. Goiffon (Paris). Dr. J. Aimard is the general secretary of the congress and may be addressed at 24 Boulevard des Capucines, Paris, IX^e.

Princess Alice Hospital, Eastbourne

The Marchioness of Hartington opened the nurses' home extension at this hospital on March 23rd.

London Homœopathic Hospital

It is proposed to provide an enlarged casualty department at this hospital for the reception and treatment of the increasing number of accident and ambulance cases.

Birmingham Children's Hospital

A babies' block is to be erected at this hospital and a public appeal made to pay for the building and equipment. Mr. Peter Bennett has promised to give £10,000 under a seven years' deed of covenant.

Research Fellowship in Medicine

The Council of the Royal Society invite applications for the E. Alan Johnston and Lawrence research fellowship in medicine which is tenable in any hospital or medical school in the British Isles. The fellow is elected for two years and receives an annual stipend of £700. Particulars will be found in our advertisement columns.

Bath Mineral Water Hospital

Mr. Sidney Robinson has offered £35,000 for the building of the projected new hospital on a site which has already been cleared. Last year he gave £5000 to meet the cost of the additional nurses' quarters, and his earlier gifts include £3000 for the erection of a new ward and £1500 to facilitate the organisation of a national research laboratory. Mr. Robinson makes his offer on the condition that building shall begin within two years.

Incorporated Society of Chiropodists

The annual dinner of the society was held on Saturday evening last at the Trocadero, the president of the society, Mr. John H. Hanby, welcoming at the reception over 200 members and their guests. The toast of the evening was proposed by Mr. Norman Lake, senior surgeon to Charing Cross Hospital, who told the story of the early struggles of the society, to which the chairman replied, recalling the steady and practical advance of recent activities, and dwelling on the good work done at the Foot Hospital. The toast of the medical profession was proposed by Sir Henry McMahon and acknowledged by Mr. W. H. Ogilvie and Dr. A. W. Oxford. Thereafter a large number of the company danced.

St. Mark's Hospital, London

The annual general meeting of the governors of this hospital was held on March 19th. Sir Percy Vincent, the Lord Mayor, presided, and, in proposing the adoption of the report of the committee of management, said that 1935, the centenary year of the hospital, had been one of great activity in all departments. The number of patients admitted to the wards had been 1129, which was the highest recorded. The income had exceeded the expenditure, but the surplus was accounted for by legacies, which could not be regarded as normal income. After a hundred years of humanitarian work in the City of London St. Mark's needed £60,000 to meet its increased responsibilities. An appeal for that sum had been launched in 1934, and £8745 had been received in response. It was proposed to build a modern nurses' home, to increase the bed complement, to provide a self-contained paying patients' block, to install a second operating theatre, and to improve the cancer research, X ray, and out-patient departments. The hospital records showed the importance of early treatment, but, owing to lack of accommodation, hundreds of cases had to be turned away, with disastrous results. The need had become so urgent that plans were on foot to begin work on the extensions, and it was hoped that the foundation-stone of the new nurses' home would be laid during the present year. The hospital was doing a noble and useful work, and he hoped it would receive the support from the public which it undoubtedly deserved.

Mr. Lionel Norbury, the senior honorary surgeon of the hospital, said that there were 201 people on the waiting-list at the present moment, and the number seldom fell below that. A considerable proportion of those 201 people were cancer patients, for whom early treatment was of the utmost importance, and it was therefore imperative that the size of the hospital should be increased at the earliest possible moment.

Medical Diary

SOCIETIES

- ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.**
WEDNESDAY, April 1st.
History of Medicine. 5 P.M. Mr. F. N. Doubleday : John Keats, Poet and Doctor.
Surgery. 2 P.M. (King's College Hospital, Denmark Hill, S.E.). Operations by Mr. C. P. G. Wakeley, Mr. J. Everidge, and Mr. H. C. Edwards. Cases will be shown, and there will be a Demonstration of Microscopic Sections, including Adenolymphomata of the Salivary Glands. 4.30 P.M., Dr. R. D. Lawrence: Sugar Metabolism in Hyperthyroidism. Mr. H. C. Edwards: The Value and Technique of Gastroscopy. Dr. R. A. McCance: Sodium Deficiency in Surgical Practice.
- WEST LONDON MEDICO-CHIRURGICAL SOCIETY.**
FRIDAY, April 3rd.—8.30 P.M. (De Vere Hotel, Kensington), Prof. Hey Groves and Mr. Sangster Simmons: Treatment of Fractures.
- WEST KENT MEDICO-CHIRURGICAL SOCIETY.**
FRIDAY, April 3rd.—8.45 P.M. (Miller General Hospital, Greenwich). Dr. F. Hudson Evans, Dr. L. W. Bain, Dr. Edward Glover, and Dr. S. S. Lindsay: That the Neurotic Patient should be Treated by His Own Family Doctor.
- HARVEIAN SOCIETY.**
THURSDAY, April 2nd.—8.30 P.M. (Manson House, 26, Portland-place, W.), Dr. W. E. Chiesman and Dr. G. de Bec Turtle: Hematemesis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

- UNIVERSITY OF BIRMINGHAM.**
TUESDAY, March 31st.—3.30 P.M. (General Hospital), Dr. B. C. Tate: Demonstration of Skin Diseases.
FRIDAY, April 3rd (Queen's Hospital), Prof. W. Gemmill: Demonstration of Surgical Cases.
- ROYAL INSTITUTION, 21, Albemarle-street, W.**
TUESDAY, March 31st.—5.15 P.M., Prof. Edward Mellanby, F.R.S.: Drug-like Actions of Some Foods.
- INSTITUTE OF HYGIENE, 28, Portland-place, W.**
WEDNESDAY, April 1st.—3.30 P.M., Dr. R. Fortescue Fox: Arthritis in Women.
- CHADWICK LECTURE.**
THURSDAY, April 2nd.—8.15 P.M. (Royal Institute of British Architects, 68, Portland-place, W.), Mr. Lionel Pearson: Modern Hospital Construction.
- BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane-road, W.**
MONDAY, March 30th.—11.30 A.M., Prof. F. R. Fraser: Tuberculosis Complicating Pregnancy.
TUESDAY.—2.30 P.M., Dr. King: Hepatic Function and Jaundice.
WEDNESDAY, April 1st.—Noon, Clinical and pathological conference (medical). 2.30 P.M., Clinical and pathological conference (surgical). 3.30 P.M., Mr. Aleck Bourne: Disproportion and Difficult Labour.
THURSDAY.—2.15 P.M., Dr. Duncan White: Radiological Demonstration. 3 P.M., Dr. Chassar Moir: Operative Obstetrics.
FRIDAY.—Noon, Dr. A. A. Davis: Gynaecological Pathology. 3 P.M., Dr. Alan Moncrieff: Hygiene of the New-born Child. 5 P.M., Sir James Walton: Surgical Aspects of Dyspepsia.
 Daily, 10 A.M. to 4 P.M., medical clinics, surgical clinics or operations, obstetric and gynaecological clinics or operations.
- FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.**
MONDAY, March 30th, to SUNDAY, April 5th.—**INFANTS HOSPITAL, Vincent-square, S.W.** All-day course in infants' diseases. Mon., Wed., and Fri., 8 P.M., primary F.R.C.S. course (anatomy and physiology).—**NATIONAL TEMPERANCE HOSPITAL, Hampstead-road, N.W.** Wed., Dr. Reginald Lightwood: Recent Views on Anæmia in Childhood. Fri., 8.30 P.M., Dr. Lightwood: Rational Prescribing for Children. Sat. and Sun., all-day course in general medicine and surgery.—**WEST END HOSPITAL FOR NERVOUS DISEASES, Gloucester-gate, Regent's Park.** Tues., 8.30 P.M., Fundus Oculi Demonstration by Mr. Lindsay Rea for M.R.C.P. Candidates. Courses are open only to members of the Fellowship.
- HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.**
WEDNESDAY, April 1st.—2 P.M., Dr. Bertram Shires: Radiography of the Chest. 3 P.M., Dr. G. H. Newns: Pulmonary Diseases. Morbid Anatomy Demonstration.
 Out-patient Clinics daily at 10 A.M. and ward visits at 2 P.M.
- NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westminster-street, W.**
TUESDAY, March 31st.—5.30 P.M., Dr. B. T. Parsons-Smith: Oedema and its Treatment.
- MANCHESTER ROYAL INFIRMARY.**
TUESDAY, March 31st.—4.15 P.M., Dr. A. Ramsbottom: The Treatment of Peptic Ulcer with Special Reference to Larostidin.
FRIDAY, April 3rd.—4.15 P.M., Dr. F. R. Ferguson: Demonstration of Neurological Cases.
- ANCOATS HOSPITAL, Manchester.**
THURSDAY, April 2nd.—4.15 P.M., Clinical Meeting.
- GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.**
WEDNESDAY, April 1st.—4.15 P.M. (Royal Samaritan Hospital for Women), Dr. John Gardner: Prolapse.

Appointments

- ALLEN, H. W., D.M. Oxon., D.P.H.,** has been appointed Medical Registrar at the Prince of Wales's General Hospital, London.
- BADENOCH, A. W., M.D. Aberd., F.R.C.S. Eng.,** Surgical Registrar at the Metropolitan Hospital, London.
- BLAND, J. O. W., M.D. Camb.,** Senior Demonstrator of Bacteriology at St. Bartholomew's Hospital, London.
- BOYCOTT, J. A., B.M. Oxon.,** Assistant Bacteriologist to St. George's Hospital, London.
- BREWER, H. F., M.D. Camb.,** Clinical Pathologist to St. Bartholomew's Hospital, London.
- CLARKE, J. H., M.D., D.P.H.,** Medical Officer of Health for the County of Lincoln (Kesteven).
- CRUICKSHANK, ALEXANDER, M.B. Aberd., F.R.C.S. Eng.,** Surgical Registrar at the Prince of Wales's General Hospital, London.
- CUTHERBERT, J. A., M.B. Edin., D.P.H.,** Assistant Medical Officer of Health for Dundee.
- DEVLIN, W. L., M.B. Belf., D.P.H.,** Assistant Medical Officer for Rhondda.
- REBURN, CYRIL, M.R.C.S. Eng.,** Second Assistant Pathologist at the Royal Sussex County Hospital, Brighton.
- ROUGEHEAD, J. A., M.B. Glasg., D.P.H.,** Medical Officer of Health to the Burton Latimer, Desborough, and Rothwell Urban Councils, the Kettering Rural District Council, and Assistant Medical Officer to the Northants County Council.
- TODD, T. F., M.S. Lond., F.R.C.S. Eng., M.C.O.G.,** Hon. Assistant Gynaecologist to the Royal Hospital, Salford.
- WINTERTON, W. R., M.B. Camb., F.R.C.S. Eng., M.C.O.G.,** Assistant Surgeon to the Hospital for Women, Soho-square, London.
- Sheffield Royal Hospital.*—The appointment of the following Clinical Assistants is announced:—
LUDDLAM, G. B., M.B. Edin., D.L.O., Ear, Nose and Throat Department;
FAULKNER, S. H., M.D. Belf., M.R.C.P.I., D.O.M.S., Ophthalmic Department; and
KEMP, F. H., M.B. Birm., X Ray Department.
- Certifying Surgeons under the Factory and Workshop Acts:** Dr. J. T. MOFFAT (Coggeshall District, Essex); Dr. T. H. MCLEOD (North Walsham District, Norfolk).
- Medical Referee under the Workmen's Compensation Act, 1925:** C. W. GRAHAM, M.B., F.R.C.S., of Edinburgh, for all Sheriff Court Districts at present comprised in the Sheriffdoms of Fife and Kinross; the Lothians and Peebles; and Stirling, Dumbarton, and Clackmannan; with a view to his being employed in ophthalmic cases.

Births, Marriages, and Deaths

BIRTHS

- ADAM.**—On March 16th, the wife of Dr. W. Blane Adam, of Crowborough, of a daughter.
- BYROM.**—On March 19th, at Muswell Hill, Kathleen, wife of F. B. Byrom, a daughter.
- CONYERS.**—On March 16th, at Sutherland-avenue, W., the wife of J. H. Conyers, F.R.C.S. Eng., of a son.
- DAVENPORT.**—On March 17th, at Welbeck-street, the wife of Robert Davenport, F.R.C.S. Eng., of twin sons.
- DAVIDSON.**—On March 13th, in London, the wife of Dr. James Davidson, Brampton-grove, N.W., of a daughter.
- DAVIES.**—On March 17th, at Walmer, the wife of Dr. D. A. Davies, of a daughter.
- DAY.**—On March 14th, at Norwich, the wife of Dr. George H. Day, of a son.
- JACKSON.**—On March 19th, to Marjorie (née Kerr), wife of H. B. Jackson, M.B., M.R.C.P. London, of Sheringham—a daughter.
- MARKS.**—On March 20th, the wife of Dudley P. Marks, M.B. Camb., F.R.C.S. Eng., of Stratford-on-Avon, of a daughter.
- PAGAN.**—On March 15th, at Southampton, the wife of Dr. A. T. Pagan, of a son.
- SPICER.**—On March 14th, at Southsea, the wife of Captain W. R. C. Spicer, R.A.M.C., of a son.

MARRIAGES

- KNOX—CRUST.**—On March 21st, at St. Bartholomew the Great, Robert Knox, M.D. Lond., of Cambridge, to Lynda Crust, of Miningsby.

DEATHS

- BOWER.**—On March 19th, at Avenue Mansions, N.W.3, William Bower, M.B. Camb., late of Ware and Hendon.
- DODWELL.**—On March 18th, at Albert Bridge-road, S.W., Philip Rashleigh Dodwell, M.D. Lond., in his 73rd year.
- EAMES.**—On March 13th, at Derby, Ernest Victor Eames, L.R.C.P. Edin., late of Heanor, Derbyshire.
- HANSON.**—On March 21st, in London, in motor-car accident, Dorothy Mable Hanson, M.B. Liverp.
- LOW.**—On March 21st, at Singapore, consequent on a fall, John Meredith Low, M.R.C.S. Eng., Capt., R.A.M.C.
- SHADWELL.**—On March 21st, at Richmond, Arthur Shadwell, M.D. Oxon., F.R.C.P. Lond., aged 81.
- TWEEDIE.**—On March 18th, Alexander Robert Tweedie, F.R.C.S. Eng., late Colonel R.A.M.C., T., ret'd., of Nottingham.
- WHITAKER.**—On March 22nd, suddenly, at Farncombe, Surrey, Sir James Smith Whitaker, M.R.C.S. Eng., late Senior Medical Officer to the Ministry of Health, in his 71st year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

THE ART OF MEDICINE¹

BY CHRISTOPHER HOWARD, M.R.C.S.

EARLY DIAGNOSIS: TREATMENT OF PNEUMONIA

To make an early diagnosis is often to win half the battle in a case of serious illness, for as a rule treatment only fails because it is not administered sufficiently soon. Take, for instance, early pneumonia. In this disease there may be no chest signs to commence with, except widespread pain, but there are, I think, three signs which, if present, enable one to make a definite diagnosis and so to free one's mind of the incubus of the unknown. The first is the working of the nostrils, which is present even when there may be no very obvious respiratory embarrassment; and it is a sign which the best of physicians I have met, the late Dr. Ogle, continually impressed upon his clerks. The second is a pungent burning skin, which is immediately felt by the trained hand, and which may exist in the absence of a very high temperature, and for which I have never heard any adequate physiological explanation. And the third is the complete absence of chlorides from the urine. These three signs form a valuable trinity to remember, for the more one practises physic the greater is the realisation that one physical sign is worth half a dozen symptoms.

I sometimes think that of the great systems of the body it is the respiratory which has lagged behind in spectacular methods of treatment, for though the amelioration of tuberculosis of the lung is much for which to be thankful, the method is, broadly speaking, the same as that practised in the sunlit groves of a Greek temple; only now instead of worshipping Æsculapius, we kneel to the great god Laboratory. Pneumonia still, by right of facts and statistics, bears the title of Captain of the Men of Death, originally given to it by John Bunyan, and a careful study of the literature, especially that pertaining to the use of serum in this disease, does not convince me that treatment has improved in the last half-century. Expectant treatment, which means carefully observing and assisting the various processes by means of which immunity is eventually established, goes on quietly saving lives, whilst one after the other of the so-called specific treatments arise, with a flourish of manufacturer's trumpets, and all too soon, in relation to the expectations aroused, pass into the limbo of forgotten things. When people lived normal, out-of-door country lives, pneumonia, and to a greater extent still, tuberculosis, were not common diseases, but when they herded together into factories at the end of the eighteenth and the beginning of the nineteenth centuries, and the townships, which are now blots on the surface of the earth, formed themselves, tuberculous disease, especially in the lungs, spread like a forest fire. The greatest contribution of medicine towards the defeat of this disease has really been an endeavour to put people back into the country for a longer or a shorter period of time, and gradually to teach the people to say, with John Donne, that "cities are sepulchres and they who dwell there are carcases."

In the treatment of pneumonia, one should use morphia in the same way as a revolver, that is to say, never until it is necessary, and then properly; for both morphia and the revolver, if properly used, need not be employed again. One night's rest and freedom from pain, following the exhibition of an adequate dose, is far more helpful than the partial relief to be obtained from repeated small doses. For the early stages of pneumonia, as well as for large areas of pleurisy, our two most valuable and safest therapeutic aids are morphia and leeches, but

for æsthetic reasons the latter are far too little used. Some while ago I came across an old leech woman who for many years had made a good living from a leech farm somewhere down in the Cotswolds. She was now living on an old-age pension, and bereft of other means of resource, because the fashion for the use of leeches has so completely disappeared. I do not know whether she was a typical *laudator temporis acti* but she told me that leeches had joined in the general decay of the world, and no longer bit or swallowed as they used to do. My own impression is that the leeches we used in the hospital ten or fifteen years ago were better at their job than those which to-day I occasionally hire from the chemist.

MECHANICAL ASSISTANCE TO DIAGNOSIS

"In the early diagnosis of empyema, radiological signs are inferior to physical signs, and in three of our cases pus was aspirated from the pleural cavity on clinical grounds before any change was demonstrable in the X ray film." I take this sentence from a recent and valuable article on the pneumonias, which appeared in THE LANCET, for there is a widespread and childlike faith in X ray examinations, many regarding such examinations as infallible. Claude Bernard, the French physiologist, used to say that when you meet with a fact opposed to prevailing theory you should adhere to the fact and abandon the theory, even when the latter is suggested by great authorities and generally adopted—but it is of imperative importance in medicine to be certain of one's facts. I have seen an obvious case of pneumonia denied its correct diagnosis because an X ray examination revealed nothing, and it was only after considerable probing that it was found that the picture had been taken with the wrong type of tube and was therefore useless. Similarly, I have heard of an obvious case of typhoid fever being deprived of its name because an agglutination test was negative; which reduces enteric from the status of a syndrome to that of a peculiarity and particularity of a given specimen of blood-serum. It is more important to delineate a likeness when making a diagnosis than to allow treatment to await the result of a bench test.

When the radiograph first came into general use, the older and wiser physicians fought a rearguard action against too rapid a surrender of the individual's skill in examining by sight and sound but much of this teaching has died with the teachers. The X ray is of such supreme value in so many differing conditions, that we must needs remind ourselves that it is not infallible, and that the attainment of skill in auscultation and percussion, which in its apotheosis takes many years, is still necessary. The man will always beat the machine except when reason is deserted and faith only remains. Then, just as in the days of Laennec's stethoscope, the magic tube will be invested with healing as well as with diagnostic properties.

Emerson's statement that the end of the human race will be that it will eventually die of civilisation has a particular bearing also upon the science of medicine, for in every sphere the replacement of the man by the machine must eventually result in sterility. It is therefore of interest to learn that various teaching centres are now inaugurating lectures and courses in the science of medicine, for there are at last a few people who are beginning to realise that there is little value in the student who can discourse learnedly on the hydrogen-ion concentration of the blood, and yet cannot, by the naked eye, differentiate between a nephritic and a diabetic urine. More reliance upon the use of the eyes and the fingers, and less upon the laboratory, will pay us a dividend of success both in diagnosis and treatment, and to further this end I think that a general practitioner should be appointed to give lectures in every teaching hospital.

¹ Abstract of an address delivered on Feb. 27th, 1936, before the Hunterian Society of St. George's Hospital.

The only times that a physician should close his eyes are when he is using a stethoscope or palpating, for if the mechanism of the sense of sight is temporarily not used, the other senses gain in acuity. Usually it is as well to watch the patient's expression during the whole course of the examination, but as neither the stethoscope nor the bulbs of the fingers (never use the tips) are productive of pain, it is infinitely worth while to become momentarily blind, for then all things, such as diastolic murmurs and liver margins, shall be added unto you. In a famous book on diseases of the gall-bladder, it is stated that a physician literally carries his brains at the tip of his fingers, which is delightful, and in the case of many physicians whom I know would be, from the point of view of quantity, more than a possible conception: but such statements strengthen one's opinion that the word "literally" is responsible for even more lapses in literature than the much-abused words "unique" and "meticulous."

"Look before you feel" should be one of the frequently recurring texts of anyone who aspires to teach medicine. The novice and the indifferent doctor always press, probe, and pummel as the first step to a diagnosis, and this way disaster lies. The clue to the inflamed appendix is found by noting the restriction in the movement of the abdominal wall, not in the imposition of two hundred pounds of doctor on to the patient's belly, accompanied by a naive inquiry as to whether it hurts. Often the presence of blood inside the peritoneum can be deduced from a small area of bruising appearing on the abdominal skin. Such a sign is sometimes difficult to see unless the whole abdominal wall is examined with a strong light, but when found it is very suggestive, and may indeed be pathognomonic.

THE DIAGNOSTIC VALUE OF PAIN

It is never too late and never too early to remind ourselves how deceptive may be the site of pain. Many people who suffer from pain in or over the heart are convinced that they have some fell cardiac disease and they are too frightened to consult a doctor and to learn the truth, which is that cardiac pain is more often a symptom of disease in the gall-bladder or liver than in the heart itself. The reverse, of course, also holds true, and for example pain in the lower jaw, usually the left side, may be a sign of heart disease, as also may be the sensation of having a lump in the gullet. One perhaps need not hasten to add that in themselves neither of these signs is of any value, and is only to be taken in conjunction with all the minutiae which go to make up a clinical picture and so point to the diagnosis. When a patient comes into my consulting-room complaining of a pain in the heart region, I lay myself long odds against the presence of any cardiac lesion. Shortness of breath, swelling of feet, irregular pulse, indigestion, blueness or clamminess of the skin, nausea and giddiness, mental change, and a thousand others, are the complaints of heart cases. It is astonishing how badly disorganised a heart may be without giving rise to pain. The inevitable exception, of course, is furnished by angina, and there, though the pain is absolute agony, the fear of impending, sudden, and dramatic death is even more alarming.

It is very important to differentiate between gall-bladder disease and affection of the coronary arteries, which is sometimes more difficult than it sounds. Nearly 50 per cent. of cholecystitic cases, whether or not complicated by the presence of stones, give a story of more or less pain in the heart. This awareness of the precordial region may show all degrees from occasional palpitation to attacks of pseudo-angina. If evidence incriminating either the gall-bladder or the vascular supply of the heart is hard to evaluate, help may often be obtained from an electrocardiograph where the presence of a flattened or inverted T wave may aid in the differential diagnosis, and in so doing will furnish us with one of the comparatively rare occasions in which an

electrocardiographic tracing is of practical value in general medicine.

It is probable that a really acute attack of sciatica furnishes the most agonising pain to which a healthy man or woman in comfortable circumstances is liable, and I still think that in spite of many other vaunted remedies the best treatment is to give morphia, a quarter of a grain, repeated perhaps for three nights in succession, and that this treatment will sometimes see the end of an attack. There is no reason to suppose that the drug has any specific effect upon the inflamed nerves, but it gives rest to the tortured body, and in this rest the affected nerves must share. Old-fashioned but still popular textbooks, warn us against prescribing morphia in such cases, but I think their authors forget that it is to all intents and purposes impossible for a layman to obtain morphia and therefore the risk of causing an addiction is minimal, and it is my firm belief, from experience in my own practice, that the easily obtained barbiturates are far more dangerous and much less effective as a prescription.

[After some shrewd remarks upon influenza as seen in private practice, when the characteristic features of the pain must be noted, Dr. Howard went on to say that there may be a diagnostic sense enabling some to escape the danger of prescribing the wrong drug or making mistakes in dosage, but the allergic states constitute, he pointed out, a real danger which may beat the prescriber of the most simple drugs. He said:—]

Quinine is a common offender, but I think the most poisonous substance I have come across when ingested by a particular patient, was any form of potato. Even minute quantities, used for instance to thicken a soup, produced immediately profound collapse. Potato is not common, but eggs are quite common as instigators and inciters of these anaphylactic reactions, and no amount of desensitisation appears to have more than a temporary effect. Another drug commonly giving rise to untoward reactions is iodine, and now that in various forms it is widely advertised for external application, and that to its very presence next to the skin in the form of a locket or socks is being attributed a miraculous healing power, it is well to remember that even in minute quantities iodine may be a poison. If only a slight susceptibility exists, nothing but a running nose and red eyes may be noticed but a more pronounced reaction may be evidenced by a severe rash covering all the surface of the body. Iodine is excreted as iodide in the urine, sweat, saliva, milk, and the secretions of most of the glands, and there is a curious fact to remember, that the intensity of the reaction is often inversely proportional to the amount absorbed. People object to the administration of drugs which upset them or which give them an ugly, spotty, and blotchy skin, but it is not until one has examined a good many patients for a good many years that one begins to realise how rare it is to see a really lovely skin. The woman patient who had the most perfect skin I ever saw was almost a moron, so presumably the ectoderm exhausted itself on its attainment and had little left in hand for the highest nerve centres.

Itching of the skin is difficult to treat and is not a very common complaint, though of course localised itching, such as pruritus ani, is a very common complaint. It is usually badly treated and the patient continues to excoriate himself until a second infection is superadded and the misery of itching is intensified by the presence of discharge. The rational treatment consists first in the cure by injection of any internal hæmorrhoids, and the diminution of local congestion consequent upon this step leads in about half the cases to a cure of the pruritus. If, however, the skin, by scratching and secondary infection is hypertrophic and obviously involved, the whole area should be painted with solution of camphor and iodine in spirit until it becomes harder and less inflamed. Then a few injections of benzyl

benzoate in oil may give relief. This relief is likely only to be temporary unless the peri-anal skin is treated carefully for at least a year. There are many varieties of continuation treatment, but the most effective of the important directions are, first, that the area must be washed after every motion, and then La Rola must be carefully rubbed in. This is a patent preparation for which I can find no substitute. Every night the area should be dabbed with witch-hazel. No powder of any sort should be allowed and no dietary rules, except of course in the case of diabetics, are of value. All ointments are useless, but in some cases amazing relief can be given and permanent cure obtained by extracting 2½ c.cm. of blood from a vein in the anti-cubital fossa, mixing it with an equal amount of 2 per cent. novocain, and injecting it carefully, subcutaneously, into the peri-anal area. Personally I think that auto-hemotherapy in its varying forms is far too little used in England, and for various diseases of allergy, and for such conditions as migraine, and for vague forms of petit mal, it offers a useful field of therapeutic endeavour.

COSMETIC SURGERY

I confess that as yet I do not consider that æsthetic shortcomings fulfil the conditions which should be present before the continuity of the flesh is broken. At a clinic in Paris I have seen queues of middle-aged women, all of whom had recently had their faces lifted, their noses altered, their eyelids tightened, or their breasts raised. With the Psalmist they might inquire of Providence for how long they had recaptured a faint semblance of youth, for at best the fancied improvement can only be obtained for a very few years. When I asked some of them their reason for submitting to these painful manoeuvres they rather archly replied that it was a question of *l'amour*, but I rather fancy that *amour propre* is a better reason, because there is something in the misfortunes of our friends which is not displeasing to us

POPULAR MISCONCEPTIONS

It would be impossible to enumerate all the popular misconceptions about the functioning of the body, but the following are a few to which many people still cling with conviction and sometimes emphasis.

(a) That insomnia is dangerous to health and leads to mental exhaustion and insanity. There is no jot or tittle of proof that such is the case, and though bodily rest is essential, mental oblivion, even apparent, is not necessary to recurrent and adequate activity of the mind. The amount of sleep required by a given organism varies between very wide limits. The best brain workers and those who by the world's standards are acclaimed as great, often sleep very little. I am not in the least advocating less sleep, but you will be told by your patients that insomnia is necessarily harmful, and this is a boggy that should be laid.

(b) That overwork leads to a nervous breakdown. Brain work itself never leads to any damage of the nervous tissue, but five minutes' fear, or a day's worry, which is civilisation's substitute for fear, may affect a person permanently and irreparably for the worse.

(c) That a carefully planned diet is essential to health. With obvious exceptions, such as sufferers from diabetes or peptic ulcers, the ordinary mixed diet provides such a wealth of the necessary factors, including salts and vitamins, that any alteration is much more liable to do harm than good. It has only lately been shown that it is possible to have too many vitamins, just as it is possible to have too few, but only those unfortunates who exist on the hunger line need fear that that great chemical synthetic machine, the body, will be unable to extract from the ordinary mixed diet exactly what is required for the complete and proper functioning of each and every organ.

(d) That modern life is too strenuous. Hueffer once wrote a book called "Ladies Whose Bright Eyes," and in it gives a good picture of the rigours of the Middle Ages, and the largest executive in the biggest office, surrounded by twenty telephones and a hundred typists, will be less fatigued at the end of the day than the same

man would be after five minutes in the galleys, or an hour at the court of Imperial Spain.

(e) That, and it is a most popular misconception, constipation is the root of all evils. Except in the rarest cases, the sequels of constipation are all subjective phenomena, and the headache and the lassitude are entirely due to self-suggestion. The mass suggestion of the advertisers is a sufficient reason for the auto-suggestion.

Some of your patients who fancy that they suffer from any of these five health misconceptions will want you to advise treatment at a spa. The habit of going to a spa to undergo what is optimistically known as a cure is probably a survival of the days when magic healing properties were attributed to certain places, often wells or springs situated, preferably, in a part of the country difficult of access. To make a pilgrimage in search of health is a real exercise, and the necessity of taking certain steps and of undergoing certain ritual performances fixes the idea of a cure so firmly in the sufferer's mind that the stage is set prettily for the worked for and expected result. An odd commentary on spas in general is provided by the fact that the inhabitants of such places seldom, if ever, drink the nauseous waters or undergo the ritualistic ablutions themselves, but perhaps like Jeremiah they question whether there is any balm in Gilead. To Jeremiah's further question as to the presence of a physician they can return a strongly affirmative answer, for in this respect as a profession we retain a trifle of our priestly function, and the healing waters cannot usually be obtained, externally or internally, without the *laissez passer* of one of the many spa doctors. I suppose that for people of a gouty and plethoric nature some temporary good must come from an annual pilgrimage to a place where diet and régime and magical waters are to hand, and the yearly treatments may do something to delay what one writer has so aptly called that slide in ugly anguish from vaccines and bedpans to the tomb. Having, for my sins, smelled the waters at some spas both at home and abroad, I confess that I find a feeling of great sympathy for Samuel Butler when he said that "when the water of a place is bad it is safest to drink none that has not been filtered, either through the berry of a grape or else a tub of malt. These are the most reliable filters yet invented." When, however, patients are becoming a nuisance and are wearying, it is one way of escape to send them to a spa.

I have noticed that clever people are usually fools about their own health. The nice clever people, those who have great gifts and an accompanying simplicity of soul, fall into the hands of charlatans and dishonest healers because, knowing nothing of objective pathology, they will accept any statement or treatment which the quack likes to suggest. One can love this type even though at times a considerable irritation is produced by some further piece of evidence of stupidity. The difficult and rather worthless type is the successful, usually rich, person, who having differentiated himself from the common herd by the amassing of money, or the purchase of a title, must needs be individual in his therapeutic adventures. The common basis for the absolute and stupid faith which such a man exercises in respect to some new treatment is conceit, for he cannot bear to be as other men are and must always know better than the ordinary mortal. Examples of this stupidity, of this Athenian demand for some new thing, are so numerous that I will not attempt to chronicle them, but every practitioner probably hears of a case of this sort about once a month; such as that of a patient who after a colostomy for an inoperable growth goes to a quack, and as a result attributes his improving health to the new remedies and not to the cessation of septic absorption and of obstruction consequent upon his colostomy. During this brief period of feeling better he harries his friends until they too are shepherded into the false fold. Then when the growth slowly progresses and the sufferer, after going more or less rapidly downhill,

crawls away to die quietly, he is either too ashamed or too callous to revoke the glowing testimonials he had previously broadcast.

Dr. Howard concluded with some amusing examples of the distrust among medical men of innovations, and the confidence of the public in the veteran practitioner. These people, he said, are apt to exclaim with Oliver Wendell Holmes that "Age lends the graces that are sure to please." I looked up the rest of the quotation and have now memorised it as a retort when I am next told that an older doctor is preferable, for I find the ensuing line is, "Folks want their doctors mouldy, like their cheese."

PSYCHOLOGY FOR MEDICAL STUDENTS

ADDRESSING the Medical Society for Individual Psychology on March 12th, Sir WALTER LANGDON-BROWN spoke of the efforts being made to provide medical students with a basic training in psychology. The Curriculum Conference, of which he was a member, reported last May in favour of an elementary course of lectures towards the end of the preclinical period. The lectures at this stage, said Sir Walter, should bring the facts of psychology into relation with the student's own attempts at adjustment to daily life and environment, and they should be given by a medical man rather than a pure psychologist; for in T. A. Ross's words, "it would be extremely easy to ensure hatred of all psychology if the student were put through a serious course of academic psychology." Later, when he reached his clinical period he must be prepared to realise that imagined ills required, equally with organic ones, investigation and treatment. Such investigation and treatment called for simpler, more practical, and less specialised methods if they were to be of any subsequent value to the general practitioner. Not all mental and psychological conditions, of course, were suitable for treatment by the practitioner; the psychotic patient was often inaccessible and an obsessional state often required long and specialised treatment. But an understanding of all neuroses and psychoses, and a practical knowledge of how to treat the main bulk of neuroses with which he would later have to deal in general practice was essential for the medical student.

The conference had recommended the continuance of demonstrations in a mental hospital, but emphasised the importance of making a student familiar with the psychological aspects of *all* patients. Demonstrations should be held—by physician, surgeon, or psychologist—at least once a fortnight throughout the student's period of in-patient clerkships, and in this way the teacher of medical psychology should be able to draw upon the material in the hospital as a whole. The teaching of this subject should be woven into the ordinary teaching of medicine and surgery, and it was important that the teachers should approach their subject free from the trammels of pre-war materialistic medicine in which most of the present generation were brought up. The stimulus to provide a broader and more psychological approach to medicine was not only desired from students of psychology and reasearch; the pressure to teach the neuroses is coming from below; the students themselves were eager for it, and if they did not get it from one school they would go elsewhere.

In the subsequent discussion Dr. EDWARD MAPOTHER criticised an assumption implicit in Sir Walter Langdon-Brown's thesis—namely, that the psychoses and neuroses were two separable and distinct entities. This was not generally accepted; indeed there were good reasons why the study and perhaps the practice of the two should proceed by coordinated and coöperative methods.—Dr. HENRY YELLOWLEES maintained that the psychiatrist was in fact already successfully engaged in dealing with mental disorder of all kinds whether neurotic or psychotic. Treatment of the neuroses did not postulate a different method or viewpoint from that

of the psychoses, and there were many instances of a little knowledge being a dangerous thing.—Dr. T. A. ROSS expressed general agreement with Sir Walter's views. Many neuroses were aggravated by the accumulation of biochemical and other physiognostic data; it would be in the interests of all concerned to have the simple teaching methods applied which the speaker had described.—Dr. DAVID FORSYTH said that the methods advocated had the virtue of assisting the future medical generation to correlate the old with the new concepts in medicine.

Dr. MARGARET LOWENFELD said that experience of child psychology confirmed the urgent necessity for a new viewpoint in the treatment of nervous disorders in children.—Dr. A. T. WILSON doubted whether it was possible to teach a new mode of approach to anyone confirmed in a mechanistic philosophy of causation. Preclinical teaching should be behaviourism; the bias at present was towards the analytic—Dr. R. A. NOBLE pointed out that one of the intentions of the Curriculum Conference was to add to the existent demonstrations of and lectures in psychiatry; not in any way to replace them. Physicians' distrust of psychology would be dispelled by a recognition of the fact that to be a good medical psychologist a man must primarily and essentially be a good physician.—Dr. C. M. BEVAN-BROWN, the chairman, said that Sir Walter's propositions were generally those for the advocacy of which the Society stood. For their satisfactory achievement it would be necessary to destroy, or at least modify, the mechanistic concept. The difference between the old schools and the new was fundamentally a difference of philosophic standpoint. Hitherto the materialistic standpoint had been predominant.

AIR RAID PRECAUTIONS

IN connexion with the measures being taken to mitigate the effects of possible air-raids, the Order of St. John of Jerusalem and the British Red Cross Society have agreed to place their organisations at the disposal of both central and local governments in order to supplement official resources. We understand that the St. John Ambulance Brigade have issued a special order to their divisions all over the country making provision for the training of (1) instructors, (2) the existing rank and file of the Brigade, and (3) the general public as an auxiliary reserve. The British Red Cross Society, through its county branches, is taking similar action. Already, it is stated, over 900 officers of the Brigade, many of them medical men, have been through intensive courses of instruction in London, and many of these, having obtained their instructor's certificate, are conducting classes elsewhere. The British Red Cross Society have many hundreds of officers who are also qualified to instruct. The demand for these trained men and women is said to be rapidly increasing, for the medical officers of health of boroughs and urban districts have been officially advised to organise first aid and decontamination posts in their areas, the personnel of which will be voluntarily supplied by these trained members of the St. John Ambulance Brigade and the British Red Cross Society. Those taking the courses of the Brigade and the Society undergo examination and receive certificates. Subsequent examinations are held to ensure continued efficiency.

HYGIENE IN BRIEF

A CRITICISM often levelled at the study of preventive medicine is that, though vitally important and necessary, it is generally dull. It is thus satisfactory that however listlessly the reader may take up the authorised text-book of the St. John Ambulance Association,¹ he will be interested in spite of himself for it is packed

¹ Hygiene or the Gospel of Health. The authorised text-book of the St. John Ambulance Association. Third edition. By Neville M. Goodman, M.D. Camb., D.P.H. Lond., Lecturer and Examiner for the St. John Ambulance Association; Lecturer in Public Health and Sanitation, the London Hospital, London: St. John's Gate, Clerkenwell, E.C.1. 1935. Pp. 195. 1s. 6d.

with meat from start to finish, prepared in a palatable and digestible form. Dr. Goodman is a sane optimist. He believes, with Dr. Alfred Cox, that health can be bought and that it is not the people who make the slums. It is hard to choose quotations where so much is worth quoting, but two examples of his pithy utterances may be given. "An Englishman's home is said to be his castle; it should at least be a healthy, modern one, not an insanitary mediæval ruin." And again, "The good housewife must know where to draw the line between making her home a kind of museum of cleanliness and a slovenly abode of dirt. At either extreme her husband and family will only return home with reluctance." Appended to each chapter is a questionnaire which can be answered from the text and should prove useful to examinees.

WHITAKER'S ALMANACK

THE new edition of Whitaker's Almanack not only contains the new House of Commons and a conspectus of the National Government as reconstituted after the general election, but also the changes consequential on the death of King George V. and the accession of Edward VIII. The Almanack is thus so modern that we turned with misgiving to the title page with the signs of the zodiac, to find with relief that it remains as it always was. The Almanack is still the completest guide we have to the activities of our fellow human beings and might well be the most acceptable gift for anyone allowed to possess only one book and already familiar with the Bible and Shakespeare. By way of quotation a single item of curious information must here suffice. Contrary to general belief, of the 40 million inhabitants of England and Wales less than 1 per cent. were born in Scotland, while of the five million inhabitants of Scotland nearly 3.5 per cent. were born in England or Wales. Whitaker can be relied upon to refute many other well-worn fallacies. The price is 3s. in paper cover and 6s. in cloth.

Vacancies

For further information refer to the advertisement columns.

- Barnsley Municipal General Hospital.**—First Asst. M.O. £650.
Belgrave Hospital for Children, Clapham-road, S.W.—Two H.P.'s and one H.S. Each at rate of £100.
Birmingham, Canwell Hall Babies' Hospital.—Res. M.O. At rate of £250.
Birmingham City.—Sen. Asst. M.O.H. £750.
Birmingham City, Maternity and Child Welfare Dept.—Three Temp. M.O.'s. Each £10 per week.
Birmingham, Queen's Hospital.—Bacteriologist and Clinical Pathologist. £600. Also Res. Surg. Reg. £125.
Bolton Royal Infirmary.—H.S. £125.
Brighton, New Sussex Hospital for Women, Windlesham-road.—H.P. £100.
Bristol, Brentry Colony for Male Mental Defectives, Westbury-on-Trym.—Res. Med. Supt. £650.
Bristol, Ham Green Hospital and Sanatorium.—Jun. Asst. Res. M.O. £250.
British Postgraduate Medical School, Ducane-road W.—Three H.S.'s.
Burnley, Victoria Hospital.—H.P. At rate of £150.
Cambridge, Addenbrooke's Hospital.—H.P. Also H.S. to Special Depts. Each at rate of £130.
Cardiff Royal Infirmary.—H.S. for Ophth. Dept. At rate of £40.
Chester, East Lancashire Tuberculosis Colony, Burrowmore Hall.—H.P. At rate of £150.
Cumberland County Council.—Asst. County M.O.H. and District M.O.H. £800.
Durham County Mental Hospital.—First Asst. M.O. £594.
Eastbourne Royal Eye Hospital, Pevensey-road.—H.S. £100.
Exeter, Royal Devon and Exeter Hospital.—H.S. to Ear, Nose, and Throat Dept. At rate of £150.
Golden-square, Throat, Nose, and Ear Hospital, W.—H.S. £100.
Gordon Hospital for Rectal Diseases, Vauxhall Bridge-road, S.W.—Res. H.S. £150.
Gravesend and North Kent Hospital.—H.S. £125.
Greenwich Metropolitan Borough.—M.O.H. £1100.
Harrogate and District General Hospital.—Hon. Physician.
Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Res. Surg. O. £150. Also Asst. Res. M.O. and 3 H.P.'s. At rate of £150 and £50 respectively.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—Res. M.O. Also H.P. At rate of £150 and £100 respectively.
Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.—Res. H.S. At rate of £75.
Huddersfield Royal Infirmary.—Cas. O. £200. Also H.P. and Res. Anaesthetist. £150.
Hull Royal Infirmary.—First H.P. At rate of £175.
Iford, King George Hospital.—H.P. and two H.S.'s. Each at rate of £100.
Infants Hospital, Vincent-square, Westminster, S.W.—H.P. At rate of £75.
Ipswich, East Suffolk and Ipswich Hospital.—H.S. £144.
Kent Education Committee.—Half-time Asst. M.O. £350.
Laboratories of Pathology and Public Health, 6, Harley-street, W.—Third Asst. Pathologist. £450.
Leeds Hospital for Women.—Hon. Surgeon. Also Hon. Obstet. Surgeon.
Leeds Maternity Hospital, Hyde Terrace.—Res. Surg. O. At rate of £200. Also two H.S.'s. Each at rate of £75.
Leeds University.—Chair of Anatomy. £1000. Also Tutor in Obstetrics and Gynaecology. £500.
Liverpool Sanatorium, Delamere Forest, Frodsham.—Second Asst. to Med. Supt. £200.
Liverpool, Walton Hospital.—Res. Asst. M.O. £200.
London County Council.—Two Asst. M.O.'s (Grade II.). Each £250. H.P.'s. Each £120. Also Clin. Asst. £150.
L.C.C. Central Histological Laboratory, Archway Hospital, Archway-road, N.—Asst. Pathologist. £650.
London Lock Hospitals.—Two Res. M.O.'s. One for Male Dept. One for Female Dept. Each at rate of £175.
London University.—University Chair of Anatomy at St. Bartholomew's Hospital Medical College. £1000.
Macclesfield General Infirmary.—Second H.S. At rate of £150.
Maidstone, Kent County Ophthalmic and Aural Hospital.—Ophth. H.S. At rate of £200.
Manchester, Ancoats Hospital.—Res. M.O. At rate of £150.
Manchester, Booth Hall Hospital.—Jun. Asst. M.O. At rate of £200.
Manchester Royal Children's Hospital, Pendlebury.—Res. Surg. O. At rate of £125.
Manchester Royal Infirmary.—Registrar to Medical Out-patients. At rate of £150.
Margate, Royal Sea-bathing Hospital.—Asst. Med. Supt. £500.
Maudsley Hospital, Denmark Hill, S.E.—Asst. M.O.'s. Each £470.
Mount Vernon Hospital, Northwood.—Asst. Radiologist. £500.
National Hospital for Diseases of the Heart, Westmoreland-street, W.—Res. M.O. Also Out-patient M.O. At rate of £150 and £125 respectively.
Newport, Mon., Royal Gwent Hospital.—Cas. O. £175. Also H.S. £135.
New Zealand, Queen Mary Hospital, Hammer Springs.—M.O. £650.
Oldham Royal Infirmary.—Cas. O. and H.S. for Fracture Dept. At rate of £175.
Portsmouth Royal Hospital.—Cas. O. At rate of £130.
Preston and County of Lancaster Royal Infirmary.—H.P., Cas. H.S. Also H.S. Each at rate of £150.
Queen Mary's Hospital for the East End, Stratford, E.—Asst. Radiologist. £150. Also Obstet. H.S. £120.
Reading, Royal Berkshire Hospital.—H.P. Also Cas. O. Each at rate of £125.
Redhill, Royal Earlswood Institution.—Jun. Asst. M.O. At rate of £250.
Richmond, Surrey Royal Hospital.—Jun. H.S. At rate of £100.
Rochdale Infirmary and Dispensary.—Second H.S. £150.
Rotherham Hospital.—Cas. H.S. £150.
Royal Free Hospital, Gray's Inn-road, W.C.—Res. Cas. O. At rate of £150.
Royal National Orthopaedic Hospital, 234, Great Portland-street, W.—H.S. At rate of £150.
Royal Society, Burlington House, W.—E. Alan Johnston and Lawrence Research Fellowship in Medicine. £700.
St. Mary's Hospital for Women and Children, Plaistow, E.—Res. H.S. and Res. H.P. £155 and £150 respectively.
Salford City.—Asst. M.O. for Venereal Diseases Treatment Centre. £500.
Salford, Hope Hospital.—Res. Obstet. Officer. £400.
Salisbury General Infirmary.—H.S. At rate of £125.
Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. At rate of £100.
Sheffield Children's Hospital.—H.S. At rate of £100.
Shoreham-by-Sea, Southlands Hospital.—Second Asst. Res. M.O. £300.
Southend-on-Sea General Hospital.—Obstet. Registrar. £125.
South London Hospital for Women, Clapham Common, S.W.—Clin. Asst.
Surrey County Council.—Ophth. Surgeon. £750.
Swanley Hospital Convalescent Home, Parkwood.—Res. M.O. At rate of £200.
University College Hospital, Gower-street, W.C.—Hon. Clin. Asst. in X Ray Dept.
West London Hospital, Hammersmith-road, W.—Physician.
Wigan, Royal Albert Edward Infirmary and Dispensary.—Res. Med. and Surg. O. and Reg. £250. Also H.S. £150.
Wilkesden General Hospital, Harlesden-road, N.W.—Hon. Anaesthetist.
Yorkshire Children's Orthopaedic Hospital, Kirbymoorside.—H.S. £200.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Nelson (Lancs.).

SCARBOROUGH'S NEW HOSPITAL.—The new hospital at Scarborough, which is being built at a cost of £128,000, is to be opened in September. Between £12,000 and £15,000 is required to meet the capital expenditure. Its maintenance cost will exceed that of the present hospital, but it is hoped that a new contributory scheme, which will bring in at least £3000, will make this good.
